SUTURED MANIFOLDS
AND GENERALIZED THURSTON NORMS

MARTIN SCHARLEMANN

Over the past several years, David Gabai has developed new and powerful machinery for the study of 3-manifolds ([3]–[7]). Among the long-mysterious questions he has answered are the Poenaru conjecture, the Property R conjecture, the superadditivity of knot genus, and property P for satellite knots. It is the intention here to give an account of these developments, starting at the very beginning.

This began as an expository paper. It first became apparent that a generalization of the Thurston norm would be useful in such an exposition when it provided a direct alternative to an awkward doubling argument in [3]. Eventually it became clear that the theory of sutured manifolds could be developed from a different perspective, a perspective which is combinatorial, uses no foliations, is perhaps more general (cf. the latitude in the definition of index in 7.4), and seems to recover and extend (cf. [12]) the principal topological results. The absence of foliations simplifies the proof at several points and is perhaps interesting in its own right.

All of the central results of the paper were proven first by Gabai, with the exception of superadditivity of knot genus. This last theorem we proved simultaneously (announcements crossed in the mail). Gabai’s proof uses the machinery of [4] (§5 here) and a trick of A. Thompson [13]. The proof here is an illustration of the use of β-norms for β a 1-complex more complicated than a circle (in fact an “eyeglass”).

The paper is organized as follows: §§0 and 1 establish notation and describe the generalized Thurston norm. §2 describes sutured manifold decompositions and show that β-taut decompositions can be built on any relative homology class. §3 is essentially a careful proof of [3, Lemma 3.5]. Gabai’s original theorem is only sketchily proved and the hypotheses incomplete. Since this theorem is central to the development here (it substitutes for foliations), we give a complete statement and detailed proof. §4 proves that sutured manifold

Received December 21, 1987. The author was supported in part by a grant from the National Science Foundation.
hierarchies always exist, via the notion of complexity of a sutured manifold. Thus §§0–4 can be viewed as parallel to [3].

§5 shows that satellite knots of trivial winding number have property P. Since later we show that all satellite knots have property P this section is in some sense redundant. It is included because it is a beautiful illustration of the technique to be used, and is particularly simple because β is trivial and parametrizing surfaces are unnecessary. It is parallel to [4].

§6 contains a set of “reducing lemmas” which give criteria for simplifying the 1-complex β. §7 introduces “parametrizing surfaces” which are used to carry topological information down through a hierarchy.

§§8–10 are the main applications. §8 is a proof (somewhat generalized) of the superadditivity of knot genus under band sum. The same result is obtained in [6], though the proof is quite different. §9 is a proof that all satellite knots have property P. The combinatorics involved here (in somewhat different form) originated with Gabai’s proof of the Poenaru conjecture [5]. The application to property P is more natural, however, because of a far more obvious parametrizing surface. Finally §10 sketches how a parametrizing surface can be found sufficient to prove the Poenaru conjecture from the combinatorics of §9.

Throughout we have made no attempt to state results in their most general form, for these generalizations can be found in [3], [4], [5]. The emphasis here is rather to generalize technique and to pick particularly interesting applications as illustrations of the technique.

A reader with only a casual interest would do well to read §§0, 1, 2 (except 2.5) 3.5, 3.9, 4.18–4.19, and 5.

Topology seminars in Jerusalem and Austin and individual topologists too numerous to list have spotted errors and made suggestions on this manuscript. Particularly helpful was Cameron Gordon’s discovery of a subtle combinatorial error in §9 whose correction simplified the argument quite a bit. I am grateful to the topologists at the Instituto de Matematicas, U.N.A.M., who provided a patient and attentive audience for the first exposition of this viewpoint in December 1985.

0. Preliminaries and notation

(M, ∂M) will always be an oriented 3-manifold with boundary. β will denote a 1-complex contained in M. The collection of all valence 1 vertices of β is denoted ∂β and the inclusion of β in M is proper, meaning ∂M ∩ β = ∂β. We will henceforth reserve the term vertex of β for those vertices not in ∂β
(hence in the interior of \( M \)). The set of vertices of \( \beta \) are denoted \( \mathcal{V}_\beta \) and the set of edges \( \mathcal{E}_\beta \).

\( \mathcal{N}(\beta) \) will denote a regular neighborhood of \( \beta \), which we view as the union of 3-ball neighborhoods (0-handles) around the vertices, denoted \( \mathcal{N}(\mathcal{V}_\beta) \), and 1-handles along the edges, denoted \( \mathcal{N}(\mathcal{E}_\beta) \). In general, for any proper submanifold \((P, \partial P)\) of \((M, \partial M)\), \( \mathcal{N}(P) \) denotes a relative regular neighborhood and \( \mathcal{N}(P) \) its boundary as a regular neighborhood. Similarly \( \mathcal{N}(\beta) \) denotes the standard handlebody boundary of \( \mathcal{N}(\beta) \).

Each 1-handle in \( \mathcal{N}(\mathcal{E}_\beta) \) can be viewed as a copy of \( I \times D^2 \). A disc \( \{p\} \times D^2 \) is called a meridian disk. Similarly \( \{p\} \times \partial D^2 \) is called a meridian circle.

Proper surfaces in \((M, \partial M)\) will always be regarded as oriented and in general position with each other and with \( \beta \). In particular such proper surfaces are disjoint from \( \mathcal{N}(\mathcal{V}_\beta) \) and intersect \( \mathcal{N}(\mathcal{E}_\beta) \) only in meridian disks. Since our surfaces will always be oriented, by choosing an arbitrary orientation of an edge \( e \) of \( \beta \) it makes sense to say that two points of intersection of \( S \) with \( e \) have the same (or opposite) sign.

Denote by \( M_\beta \) the closed complement of \( \mathcal{N}(\beta) \) in \( M \). A proper surface \((Q, \partial Q) \subset (M_\beta, \partial M_\beta)\) will mean a surface in normal position with respect to the handle structure on \( \mathcal{N}(\beta) \). That is, \( \partial Q \) intersects the 0-handle boundaries \( \mathcal{N}(\mathcal{V}_\beta) \) in arcs and circles which are essential in the complement of \( \mathcal{N}(\mathcal{E}_\beta) \), and \( \partial Q \) intersects each 1-handle boundary \( I \times \partial D^2 \subset \mathcal{N}(\beta) \) in \( I \times \{ \text{points} \} \).

In particular any component of \( \partial Q \) lying in \( \mathcal{N}(\mathcal{E}_\beta) \) and isotopic to a meridian circle is isotoped off \( \mathcal{N}(\mathcal{E}_\beta) \) so that it lies in either \( \mathcal{N}(\mathcal{V}_\beta) \) or in \( \partial M \).

**Figure 0.1**
If $P$ is a manifold (of dimension 0, 1, or 2 in practice), then $|P|$ denotes the number of components of $P$ (thus $|P|$ is the cardinality of $P$ if $P$ is a finite collection of points).

1. Generalized Thurston norms

1.1 Definition. Suppose $(S, \partial S)$ and $(R, \partial R)$ are two surfaces in general position in $(M, \partial M)$. Define $R \Join S$ to be the “double-curve sum” of $R$ and $S$ (i.e., cut and paste along intersection curves and arcs to get an oriented surface representing the cycle $R + S$). $R \Join S$ is an imbedded oriented surface coinciding with $R \cup S$ outside of a regular neighborhood of the double curve set.

Let $(M, \partial M)$ be a compact, oriented 3-manifold, $N$ a subsurface of $\partial M$, and $\beta$ a properly imbedded 1-complex in $M$. Let $\chi$ denote the Euler characteristic. For a connected surface $(S, \partial S) \subset (M, N)$ in general position with respect to $\beta$ define

$$\chi_\beta(S) = \max(0, |S \cap \beta| - \chi(S)).$$

When $S$ is not connected, define $\chi_\beta(S)$ to be the sum of $\chi_\beta(S_i)$ over all the components $S_i$ of $S$. An alternative definition in terms of the Euler characteristic $\chi$ is:

$$\chi_\beta(S) = |S \cap \beta| - \chi(S) + |\text{disks in } S \text{ disjoint from } \beta|$$
$$+ |\text{spheres in } S \text{ intersecting } \beta \text{ in one point}|$$
$$+ 2 \cdot |\text{spheres in } S \text{ disjoint from } \beta|.$$
Finally, define a function $x_\beta: H_2(M, N) \to \mathbb{Z}_+$ by
\[ x_\beta(a) = \inf\{x_\beta(S)|S \text{ is an imbedded surface representing } a\}. \]

1.2 Definition. Let $(S, \partial S)$ be a properly imbedded surface in $(M, \partial M)$.
(a) $S$ is $\beta$-minimizing in $H_2(M, N)$ if $x_\beta[S, \partial S] = x_\beta(S)$.
(b) An arc or simple closed curve in $S$ is $\beta$-essential if it is essential in the punctured surface $S - \beta$.
(c) If there is a $\beta$-essential simple closed curve $C$ in $S$ which bounds a disk in $M - S$ disjoint from $\beta$, then $S$ is called $\beta$-compressible. Otherwise $S$ is $\beta$-incompressible.
(d) $S$ is $\beta$-taut if it is $\beta$-incompressible, $\beta$-minimizing in $H_2(M, \mathcal{N}(\partial S))$ and any given edge of $\beta$ always intersects $S$ with the same sign. If $\beta = \emptyset$ we say simply that $S$ is taut (in the Thurston norm).
(e) $M$ is $\beta$-irreducible if any 2-sphere disjoint from $\beta$ in $M$ bounds a 3-ball disjoint from $\beta$.
(f) $S$ is $N_\beta$-compressible if there is a disk $D$ in $M - \beta$ for which $D \cap (\partial M \cup S) = \partial D$ is the union of an arc in $N$ and a $\beta$-essential arc in $S$.

1.3 Lemma. (a) $\chi(R \setminus S) = \chi(R) + \chi(S)$.
(b) If $(S, \partial S)$ is $\beta$-minimizing in $H_2(M, N)$, then it is $\beta$-minimizing in $H_2(M, \mathcal{N}(\partial S))$ but not vice versa.
(c) $x_\beta(a + b) \leq x_\beta(a) + x_\beta(b)$.
(d) Suppose $(R, \partial R) \subset (M, N)$ is $\beta$-incompressible and $N_\beta$-incompressible. Then any surface $(S, \partial S) \subset (M, N)$ can be modified by 2-surgery, without increasing $\chi_\beta(S)$, so that, for $R'$ any collection of parallel copies (identically oriented) of components of $R$,
\[ \chi_\beta(S \setminus R') = \chi_\beta(S) + \chi_\beta(R'). \]
(e) Suppose \((R, \partial R) \subset (M, N)\) is \(\beta\)-taut. Then so is every collection of components of \(R\).

\textbf{Proof.} \(R \cong S\) is obtained from the disjoint union of \(R\) and \(S\) by removing a collection of arcs and circles and sewing them back in differently. Hence \(\chi\) is unchanged.

(b) Follows from the homomorphism \(H_2(M, \mathcal{N}(\partial S)) \to H_2(M, N)\). Figure 1.4 is an example of a surface \(S\) \(\beta\)-minimizing in \(H_2(M, \mathcal{N}(\partial S))\) but not in \(H_2(M, N)\). In fact \(\chi_\beta(S) = 1\) while \(\chi_\beta(S') = 0\).

To prove (c) and (d), consider surfaces \((R, \partial R)\) and \((S, \partial S) \subset (M, N)\) in general position. Suppose no component of \(R \cap S\) is \(\beta\)-inessential in \(R\) or \(S\). Then it is easy to see that \(\chi_\beta(R \cong S) = \chi_\beta(R) + \chi_\beta(S)\).
To prove (c) choose $\beta$-minimizing representatives $R$ and $S$ of $a$ and $b$. Repeatedly do 2-surgery on disks cut off by innermost $\beta$-inessential circles or outermost $\beta$-inessential arcs of $R \cap S$. This never increases $\chi_\beta$. Eventually $R$ and $S$ intersect only in components $\beta$-essential in both. Then $x_\beta(a+b) \leq x_\beta(R \setminus S) = x_\beta(R) + x_\beta(S) = x_\beta(a) + x_\beta(b)$.

To prove (d) first do 2-surgery on $S$ so that no circle of $R \cap S$ is $\beta$-inessential in $R$. Since $R$ is $\beta$-incompressible, no circle of $R \cap S$ (hence $R' \cap S$) is $\beta$-inessential in $S$. Similarly alter $S$ so no arc of $R \cap S$ is $\beta$-inessential in $R$ (e.g. in Figure 1.3 think of $S$ as the horizontal surface and the $N_\beta$-compressing disk as lying in $R$). Since $R$ is $N_\beta$-incompressible, no arc of $R \cap S$ (hence $R' \cap S$) is $\beta$-inessential in $S$. Then $\chi_\beta(R' \setminus S) = \chi_\beta(R') + \chi_\beta(S)$.

(e) Suppose $R$ is $\beta$-taut, let $R'$ be a collection of components of $R$ and $R'' = R - R'$. Clearly $R'$ is $\beta$-incompressible. Suppose $R'$ were not $\beta$-minimizing, and let $T$ be a $\beta$-taut surface with $[T, \partial T] = [R', \partial R']$ in $H_2(M, \mathcal{N}(\partial R'))$ and $\partial T$ parallel to but disjoint from $\partial R'$. Since $R''$ is $\beta$-incompressible, it is $N_\beta$-incompressible for $N$, the annuli $\mathcal{N}(\partial R'')$. Modify $T$ as in (d) so that $\chi_\beta(T \setminus R'') = \chi_\beta(T') + \chi_\beta(R'') < \chi_\beta(R') + \chi_\beta(R'') = \chi_\beta(R)$. This contradicts the tautness of $R$.

1.4 Theorem. (a) $x_\beta$ extends to a canonical continuous function $x_\beta : H_2(M, N; \mathbb{R}) \to \mathbb{R}_+$ which is convex, and is linear on rays through the origin.

(b) Any element of $H_2(M, N; \mathbb{Z})$ has a $\beta$-minimizing, $\beta$-incompressible representative $(S, \partial S)$ such that all intersections of $S$ with a given edge of $\beta$ have the same sign.

Proof. (a) This follows from Lemma 1(a) and [14, Lemma 1].

(b) Let $(S, \partial S)$ be a $\beta$-minimizing representative of a class in $H_2(M, N)$. Among all such $\beta$-minimizing representatives choose one with a minimal number of intersections with $\beta$. Then $S$ intersects any given edge of $\beta$ with the same orientations, for otherwise a 1-surgery on $S$ would remove two points of $\partial S \cap \beta$.

Finally, $\beta$-compress $S$ as much as possible. Neither operation increases $\chi_\beta(S)$. q.e.d.

Let $N \subset \partial M$ and $x_\beta$ be as in 1.1.

1.5 Corollary. For $a, b \in H_2(M, N)$ there is an $m \geq 0$ such that for all $k \geq 0$

$$x_\beta((a + mb) + kb) = x_\beta(a + mb) + kx_\beta(b).$$

Proof. Consider the function $\varphi : \mathbb{Z} \to \mathbb{Z}$ given by

$$n \to x_\beta(a + (n + 1)b) - x_\beta(a + nb).$$
Since $x_\beta(a + (n + 1)b) + x_\beta(a + (n - 1)b) \geq 2x_\beta(a + nb)$ by convexity, $\varphi$ is a nondecreasing function into the integers no larger than $x_\beta(b)$. Hence eventually, say for $n \geq m$, $\varphi$ is a constant $c$. Then for all $k \geq 0$

$$x_\beta((a + mb) + kb) = x_\beta(a + mb) + kc.$$  

Moreover, $x_\beta(b) = \lim_{k \to \infty}[x_\beta((a + mb) + kb) - x_\beta(a + mb)]/k = c$. q.e.d.

Now suppose that $\beta^+$ is the union of $\beta$ and a collection $\delta$ of proper arcs in $(N, \partial N)$. (Regard $\delta$ as pushed slightly into $M$.)

1.6 Lemma. Suppose $M$ is $\beta$-irreducible. If $(S, \partial S) \subset (M, N)$ is $\beta^+$-taut then it is $\beta$-taut.

Proof. First we show that $S$ is $\beta$-incompressible. Suppose a disk $(D, \partial D)$ disjoint from $\beta$ intersects $S$ precisely in $\partial D$. Isotope $D$ slightly in $S - \beta$ so that it lies entirely in the interior of $M$. Then $D$ is disjoint from $\delta$, hence from $\beta^+$. Since $S$ is $\beta^+$-taut, $\partial D$ bounds a disk in $S$ disjoint from $\beta^+$, hence $\beta$.

Next we show that $S$ is $\beta$-minimizing. Suppose $(S', \partial S')$ is $\beta$-minimizing for $[S, \partial S] \in H_2(M, N(\partial S))$. By possibly capping off annuli in $N(\partial S') - \partial S'$, which does not change $\chi_\beta(S')$, we can assume that $\partial S' = \partial S$ and, in particular, that the points of $(S' \cap \beta^+)$ are those of $(S' \cap \beta)$ together with points of $\partial S' \cap \delta = \partial S \cap \delta$. Now $\beta$-compress $S'$ until it is $\beta$-incompressible. Then any component of $\partial S'$ bounding a disk in $M - \beta$ bounds a disk in $S'$. 
Then since $\chi_{\beta^+}(S') \geq \chi_{\beta^+}(S)$ we have
\[
\chi_{\beta}(S') = \chi_{\beta^+}(S') - |\partial S' \cap \delta| + |\text{disks in } S' \text{ disjoint from } \beta \text{ whose boundary intersects } \delta| \\
\leq \chi_{\beta^+}(S) - |\partial S \cap \delta| + |\text{disks in } S \text{ disjoint from } \beta \text{ whose boundary intersects } \delta| \\
= \chi_{\beta}(S).
\]
Thus $S$ is $\beta$-minimizing.

2. Sutured manifolds

2.1 Definition. A sutured manifold $(M, \gamma, \beta)$ is a compact oriented 3-manifold $M$, containing the proper 1-complex $\beta$, with $\partial M$ decomposed into the union along the boundary of two surfaces $R_+$ and $R_-$ oriented so that $\partial R_+ = \partial R_- = \gamma$ and so that $\partial M = R_+ - R_-$. Let $A(\gamma)$ denote a collection of disjoint annuli comprising a regular neighborhood of $\gamma$, let $T(\gamma)$ be some collection of torus components of $R_+$ and $R_-$ and define $R_{\pm} = R_{\pm} - A(\gamma) - T(\gamma)$. Then $\partial M = R_+ \cup R_- \cup A(\gamma) \cup T(\gamma)$. We regard $R_+$ as the set of components of $\partial M - (A(\gamma) \cup T(\gamma))$ whose normal vectors point out of $M$, and $R_-$ as those whose normal vectors point into $M$. The symbol $R_{\pm}$ will denote "$R_+$ or $R_-$ respectively" while $R(\gamma)$ denotes $R_+ \cup R_-$. Frequently we will abbreviate $(M, \gamma, \beta)$ to simply $(M, \gamma)$.

2.2 Definition. $(M, \gamma)$ is $\beta$-taut if
(a) the ends of $\beta$ are all disjoint from $A(\gamma)$ and $T(\gamma)$,
(b) $T(\gamma)$ and $R(\gamma)$ (equivalently $R_+$ and $R_-$) are $\beta$-taut,
(c) $M$ is $\beta$-irreducible.

Remarks. (b) and 1.2(c) imply that no edge in $\beta$ has both ends in $R_+$ or both ends in $R_-$. $\beta$-tautness is unaffected by the choice of which torus components of $R_{\pm}$ disjoint from $\beta$ are counted as lying in $T(\gamma)$, since such components have trivial norm.

2.3 Definition. A decomposing-surface $(S, \partial S) \subset (M, \partial M)$ is an oriented properly imbedded surface which intersects each $T(\gamma)$ in coherently-oriented parallel essential circles and which intersects each component of $A(\gamma)$ either in circles parallel to $\gamma$ (and oriented the same way) or in essential arcs (not necessarily oriented coherently). Then there is a natural sutured manifold structure on $M' = M - S'$ (see [3, 3.2]). Denote by $\beta'$ the 1-complex $\beta - S'$. This process of constructing a sutured manifold structure on $M'$ from one on $M$ is called a ($\beta$-taut) sutured manifold decomposition (if $M(\gamma, \beta)$
is $\beta$-taut and $(M', \gamma', \beta')$ is $\beta'$-taut). It is often helpful to continue to refer to $\beta'$ as $\beta$. Note that in $M'$, $R_\pm(\gamma')$ is parallel to $R_\pm(\gamma) \approx S$. Figure 2.1 is a local picture near $\partial M$ away from $\gamma$, while Figure 2.2 is one near $A(\gamma)$.

**Figure 2.1**

**Figure 2.2**

2.4 Definition. A *conditioned* surface $S \subset (M, \partial M)$ is a properly imbedded $d$-surface $(S, \partial S) \subset (M, \partial M)$ such that

(a) all arcs of $\partial S$ in any annulus component of $A(\gamma)$ are oriented in the same direction,

(b) no collection of simple closed curves of $\partial S \cap R(\gamma)$ is trivial in $H_1(R(\gamma), \partial R(\gamma))$,

(c) any given edge $e$ of $\beta$ which intersects $S \cup R(\gamma)$ always intersects them with the same sign.

2.5 Theorem. Given:

(a) a $\beta$-taut surface $(R, \partial R)$ in a $\beta$-irreducible 3-manifold $(M, \partial M)$,

(b) a properly imbedded family of $C$ of oriented arcs and circles in $\partial M - \mathcal{N}(\partial R)$ which is in $\ker: H_1(\partial M, \mathcal{N}(\partial R)) \to H_1(M, \mathcal{N}(\partial R))$,

(c) $y$ in $H_2(M, \partial M)$ such that $\partial y = |C|$.
Then there is a surface \((S, \partial S)\) in \((M, \partial M)\) such that

(i) \(\partial S - \mathcal{N}(\partial R) = C\),

(ii) for some integer \(m\), \([S, \partial S] = y + m[R, \partial R]\) in \(H_2(M, \partial M)\),

(iii) for any collection \(R'\) of parallel copies of components of \(R\) (similarly oriented), \(S \approx R'\) is \(\beta\)-taut,

(iv) any edge of \(\beta\) which intersects both \(R\) and \(S\) intersects them with the same sign.

**Proof.** Let \(N\) be a regular neighborhood of \(\partial R \cup C\) in \(\partial M\). Let \(\delta\) be a family of properly imbedded arcs in \(N\) so that \(N - \delta\) deformation retracts to the disjoint union of \(\partial R\) and the circle components of \(C\). Let \(\delta^+\) be \(\delta\) pushed into \(M\) and \(\beta^+ = \beta \cup \delta^+\).

![Figure 2.3](image)

**Claim 1.** \(R\) is \(\beta^+\)-incompressible, \(N_\beta\)-incompressible, and \(\beta^+\)-minimizing in \(H_2(M, N)\).

**Proof of Claim 1.** Since \(R\) is \(\beta\)-incompressible and disjoint from \(\delta^+\), it is clearly \(\beta^+\)-incompressible.

To show \(R\) is \(\beta^+\)-minimizing consider \((R', \partial R')\), a \(\beta^+\)-minimizing representative of \([R, \partial R]\) in \(H_2(M, N)\). Since \([\partial R'] = [\partial R]\) in \(H_1(N)\), it follows from 1.4(b) that we can assume \(R'\) and \(\delta^+\), hence \(\partial R'\) and \(\delta\), are disjoint and, after possibly attaching annuli of \(N - \partial R'\), that \(\partial R' = \partial R\). Then since \(R\) is \(\beta\)-taut, \(\chi_{\beta^+}(R) = \chi_\beta(R) \leq \chi_\beta(R') = \chi_{\beta^+}(R')\). Hence \(R\) is \(\beta^+\)-minimizing in \(H_2(M, N)\).

To show \(R\) is \(N_\beta^+\)-incompressible, suppose there was an essential arc \(\sigma\) in \(R - \delta^+\) which, together with an arc \(r\) of \(N\), bounded a disk disjoint from \(\beta^+\). Since \(R\) is \(\beta^+\)-minimizing in \(H_2(M, N)\), 2-surgery on the disk could not reduce \(\chi_{\beta^+}(R)\) so the component \(R'\) of \(R\) which contains \(\sigma\) must be an annulus disjoint from \(\beta^+\) or a disk intersecting \(\beta^+\) once. The latter is impossible since \(\sigma\) is essential. But the former implies two boundary components of \(R'\) can be
connected by an arc in \( N \), which is disjoint from \( \delta \). Since only one component of \( \partial R \) lies in each annular region of \( N - \delta \), this, too, is impossible.

**Claim 2.** There is a class \( z \) in \( H_2(M, N) \) such that:

(a) \( \partial z = [C] \) in the exact sequence of the triple \( (M, \partial M, \mathcal{N}(\partial R)) \),

(b) \( x_{\beta^+}(z + [R', \partial R']) = x_{\beta^+}(z) + x_{\beta^+}([R', \partial R']) \) for any collection \( R' \) of parallel copies of components of \( R \) (similarly oriented),

(c) for some integer \( m, z = y + m[R, \partial R] \) in \( H_2(M, \partial M) \).

**Proof of Claim 2.** Since \( N \) is defined so that \( [C] \) is in \( H_1(N, \mathcal{N}(\partial R)) \), and \( y \) is in \( H_2(M, N) \). Now apply 1.5 to \( y \) and \([R, \partial R]\) and let \( z = y + m[R, \partial R] \). Choose \( k \) large enough so that \( R' \subset kR \), and let \( R'' = kR - R' \). Then the choice of \( z \) guarantees that \( x_{\beta^+}(z) + kx_{\beta^+}([R, \partial R]) = x_{\beta^+}(z + k[R, \partial R]) \). We have

\[
x_{\beta^+}(z) + kx_{\beta^+}([R, \partial R]) \\
= x_{\beta^+}(z + k[R, \partial R]) \leq x_{\beta^+}(z + [R', \partial R']) + x_{\beta^+}([R'', \partial R'']) \\
\leq x_{\beta^+}(z) + x_{\beta^+}([R', \partial R']) + x_{\beta^+}([R'', \partial R'']) \\
= x_{\beta^+}(z) + kx_{\beta^+}([R, \partial R]),
\]

where the last equality follows from 1.3(e) and the fact that \( R \) is \( \beta^+ \)-taut. Thus all the inequalities are equalities and

\[
x_{\beta^+}(z + [R', \partial R']) = x_{\beta^+}(z) + x_{\beta^+}([R', \partial R']).
\]

Now let \((S', \partial S') \subset (M, N)\) be a \( \beta^+ \)-minimizing surface realizing \( z \). If any pair of circle components of \( S' \cap R \) are anti-parallel in \( R \) (i.e., bound an annulus in \( R - \beta \)), then by cutting and pasting along parallel copies of the annulus, \( S' \) may be modified to remove these circle components, without altering \( \chi_{\beta^+}(S') \). Thus we can assume no circle components are anti-parallel. By Claim 1, we can further modify \( S' \) with respect to \( R \) as in 1.3(d) so that every component of \( R \cap S' \) is \( \beta^+ \)-essential in both \( R \) and \( S' \). Finally, \( S' \) can be made \( \beta^+ \)-incompressible by \( \beta^+ \)-compressions disjoint from \( R \), since \( R \) is \( \beta^+ \)-incompressible and \( M \) is \( \beta \)-irreducible; hence \( \beta^+ \) irreducible. Since \([\partial S'] \) restricts to \([C] \) in \( H_1(N, \mathcal{N}(\partial R)) \), we can assume (1.4(b)) that \( \partial S' - \mathcal{N}(\partial R) = C \). Furthermore

\[
\chi_{\beta^+}(S' \setminus R') = \chi_{\beta^+}(S') + \chi_{\beta^+}(R') = x_{\beta^+}(z) + x_{\beta^+}([R', \partial R']) \\
= x_{\beta^+}(z + [R', \partial R']) = x_{\beta^+}([S' \setminus R'])
\]

by Claim 2(b). Hence \( S' \setminus R' \) is \( \beta^+ \)-minimizing.

In fact \( S' \setminus R' \) is also \( \beta^+ \)-incompressible. For suppose \( T \) is a component of \( S' \setminus R' \), properly isotoped in \((M, N)\) so that \( \partial T \) has minimal intersection with \( \partial R \). If \( T \) is \( \beta^+ \)-compressible then, since \( T \) is \( \beta^+ \)-minimizing, \( \chi_{\beta^+}(T) = 0 \). Since \( T \) is a component of \( S' \setminus R' \), it is made up of components \( \{U\} \) of \( S' - R' \)
and $R' - S'$ glued together along curves of $R' \cap S'$. By construction each such curve is $\beta^+$-essential in both $R'$ and $S'$, and no pair of closed curves are anti-parallel in $R' - \beta^+$. Since $\chi_{\beta^+}(T) = 0$, each component of $\{U\}$ must be a $\beta^+$-incompressible annulus disjoint from $\beta^+$ or a $\beta^+$-incompressible disk intersecting $\beta^+$ once. Possibly:

(1) $T$ is a twice-punctured sphere or once-punctured disk. Then a $\beta^+$-compression of $T$ would give a $\beta^+$-compression for the component of $U$ containing a point of $\beta^+$, which is impossible.

(2) $T$ is an annulus disjoint from $\beta^+$. Then if $T$ is $\beta^+$-compressible so are the annular components of $\beta^+$ which it contains, hence the closed curves of $R \cap S$ which comprise their boundary. This is impossible since all such curves are $\beta^+$-essential.

(3) $T$ is a $\beta^+$-compressible torus disjoint from $\beta^+$.

First note that $T$ is contained in no 3-ball $B^3$ disjoint from $\beta^+$. If $T \subset R'$ or $T \subset S'$ this is obvious. If not, then suppose $T \subset B^3$ and let $\alpha$ be a circle component of $R' \cap S'$ in $T$. On the one hand $\alpha$ is $\beta^+$-essential in $R'$ and $S'$ by construction; on the other hand, any simple closed curve lying in $R' \cap B^3$ (including $\alpha$) is $\beta^+$-inessential in $R'$ since $R'$ is $\beta^+$-incompressible.

Now view $T$ as the double curve sum of copies of $R'$ and $S'$ pushed slightly off in the direction of their normal vectors, so any curve in $T \cap R'$ (resp. $T \cap S'$) is parallel in $R'$ (resp. $S'$) to a curve in $R' \cap S'$. Since $M$ is $\beta^+$-irreducible, $T$ bounds a solid torus $W$ disjoint from $\beta^+$. Since $R'$ is $\beta^+$-incompressible, each component of $R' \cap W$ is an annulus, with boundary components (oriented as $R' \cap T$) anti-parallel in $R'$. Since no two components of $R' \cap S'$ are anti-parallel in $R'$ (by construction), it follows that $R'$ is disjoint from $W$. Then any component of $\{U\}$ which came from $R'$ would be an annulus whose boundary comes from anti-parallel curves of intersection with $S'$, again contradicting the construction of $S'$. Finally, $T$ cannot lie entirely in $S'$ because $S'$ is $\beta^+$-incompressible.

Choose $k$ so large that any edge of $\beta^+$ which intersects $S' \prec kR$ intersects it algebraically with the same sign that it intersects $R$. Tube together points of intersection of opposite sign on any given edge to get a $\beta^+$-minimizing surface $S$ for which 2.5(i), (ii) and (iv) are satisfied. Now repeat the argument above on $S$ instead of $S'$, modifying $S$ so that $S \prec R'$ is $\beta^+$-taut. Then $S \prec R'$ is $\beta$-taut by 1.6.

2.6 Theorem. Let $(M, \gamma)$ be a $\beta$-taut sutured manifold and let $y$ be a nontrivial element of $H_2(M, \partial M)$. Then there exists a conditioned surface $(S, \partial S) \subset (M, \partial M)$ containing no closed separating component such that $[S, \partial S] = y$ in $H_2(M, \partial M)$, and the sutured manifold decomposition $(M, \gamma) \xrightarrow{\S} (M', \gamma')$ is $\beta$-taut.
Proof. Since \((M, \gamma)\) is a \(\beta\)-taut sutured manifold, \(R(\gamma)\) is \(\beta\)-taut. The class \(\partial y\) in \(H_1(\partial M, A(\gamma))\) can be represented by a family of oriented arcs and circles \((C, \partial C)\) in \(R(\gamma)\) so that all arcs intersect a given component of \(\partial A(\gamma)\) with the same orientation, and no collection of circles is null-homologous in \(R(\gamma)\). Let \(S''\) be the surface from 2.5 applied to \(C\) and \(R(\gamma)\). After possibly capping off oppositely oriented components of \(\partial S''\) in \(A(\gamma)\) and \(T(\gamma)\) with annuli, \(S''\) becomes a conditioned surface. Discard any closed separating components and call the result \(S\). Since the fundamental class of \(R_{\pm}(\gamma)\) is trivial in \(H_2(M, \partial M), [S, \partial S] = y\) in \(H_2(M, \partial M)\). By 2.5 and 1.3(e) \(R_+(\gamma) \triangle S\) and \(R_-(\gamma) \triangle S\) are \(\beta\)-taut in \(M\), hence they are \(\beta\)-taut in \(M' = M - S\). This verifies 2.2(b) for \(R(\gamma')\).

To verify 2.2(c) note that a sphere in \(M - S\) disjoint from \(\beta\) bounds a 3-ball in \(M\), which is disjoint from \(\beta\). That 3-ball is disjoint from \(S\) since no component of \(S\) is null-homologous.

3. \(\beta\)-Tautness usually pulls back

Here we ask the following question: Suppose \((M, \gamma, \beta) \rightarrow (M', \gamma', \beta')\) is a sutured manifold decomposition for which \((M', \gamma')\) is \(\beta'\)-taut. When is \((M, \gamma)\) \(\beta\)-taut? Surprisingly, it almost always is.

3.1 Definition. For \(S\) a connected surface, \((\Lambda, \partial \Lambda) \subset (S, \partial S)\) a properly imbedded 1-manifold whose fundamental class is trivial in \(H_1(S, \partial S)\), and \(x_0\) a point in \(S - \Lambda\) define the potential \(\Xi_\Lambda: S - \Lambda \rightarrow \mathbb{Z}\) to be the function which assigns to any \(y\) in \(S - \Lambda\) the algebraic intersection with \(\Lambda\) of a path from \(x_0\) to \(y\). A different choice of path will make no difference in \(\Xi_\Lambda\) since the algebraic intersection of a cycle with \(\Lambda\) is always trivial. The variance \(\xi_\Lambda\) of \(\Lambda\) is the maximum, over all \(y, z\) in \(S - \Lambda\), of \(|\Xi_\Lambda(y) - \Xi_\Lambda(z)\)| and is clearly independent of \(x_0\).

3.2 Lemma. Suppose \((T, \partial T)\) and \((S, \partial S)\) are properly imbedded surfaces in general position in the 3-manifold \((M, \partial M)\), and \(T\) is homologous rel \(\partial\) to a surface in \(M\), which is disjoint from the interior of \(S\). Then

(a) \(\Lambda = T \cap S\) has trivial fundamental class in \(H_1(S, \partial S)\),
(b) for \(k\) the variance of \(\Lambda\) in \(S\), \(T \triangle kS\) is properly isotopic to a surface disjoint from \(S\).

Proof. (a) follows from standard homology theory: \(\Lambda\) is homologous in \(S\) to a family of arcs in \(\partial S\).

To prove (b), let \(C_0\) and \(C_k\) be respectively the components of \(S - \Lambda\) of the lowest and highest potential. Let \(\mathcal{N}(S)\) be a regular neighborhood of \(S\) in \(M\), viewed as a bicollar of \(S\). Then after isotoping the image of \(C_0\) in \(T \triangle S\)
to one end of the bicollar $\mathcal{N}(S)$ and the image of $C_k$ in $T \times S$ to the other (see Figure 3.1), the variance of the 1-manifold $(T \times S) \cap S$ will be $k - 1$. Repeat $k$ times; then the variance is trivial, hence the surfaces are disjoint.

![Figure 3.1](image)

**3.3 Corollary.** Suppose $(S, \partial S) \subset (M, \partial M)$ is a surface in general position with respect to the properly imbedded 1-complex $\beta \subset M$. Let $M'$ be the complement in $M$ of a bicollar $\mathcal{N}(S)$ of $S$ with ends $S_{\pm}$, and $\beta' = \beta - \mathcal{N}(S)$. If $S_+$ and $S_-$ are $\beta'$-taut in $M'$, then $S$ is $\beta$-taut in $M$.

**Proof.** If $S$ were $\beta$-compressible, then a compressing disk would have interior disjoint from $S$ and $S_+$, or $S_-$ would be $\beta$-compressible in $M'$. Hence $S$ is $\beta$-incompressible.

If an edge $e$ of $\beta$ intersects $S$ in points of opposite sign, then the subarc of $e$ between those points would have both ends on $S_+$ (or both on $S_-$) contradicting the $\beta'$-tautness of $S_+$ (or $S_-$). Thus we can assume all points of intersection with $S$ of any given edge of $\beta$ have the same sign.
It remains to check that if \( S_+ \) and \( S_- \) are \( \beta \)-norm minimizing, so is \( S \). Therefore suppose \((S', \partial S') \subset (M, \mathcal{N}(\partial S))\) is homologous to \( S \) in \( H_2(M, \mathcal{N}(\partial S)) \). We need to show that \( \chi_{\beta}(S') \geq \chi_{\beta}(S) \).

**Claim.** If \( S' \cap S = \emptyset \), then \( \chi_{\beta}(S') \geq \chi_{\beta}(S) \).

**Proof of Claim.** We will assume \( S \) is closed, for the general case is similar. Let \( \overline{S} \) denote the oriented surface \( S \cup -S' \). Then \( [\overline{S}] \) is trivial in \( H_2(M) \). Suppose \( C \) is a component of \( M - \overline{S} \) which can be oriented so that \( \partial C \) consists of a collection of components of \( \overline{S} \) with their given orientation. With no loss, assume that \( (\partial C \cap S)_+ \) lies in \( C \). Observe the following:

(a) If \( \partial C \subset S' \), then removing \( \partial C \) from \( S' \) will not change \([S']\) and can only reduce \( \chi_{\beta}(S') \). Thus it suffices to prove the claim with \( \partial C \) removed from \( S' \).

(b) If \( \partial C \subset S \), then because the orientation of \( \partial C \) agrees with that of \( S \), \( C \) contains a null-homology of \((\partial C \cap S)_+ \). Since \( S_+ \) is \( \beta' \)-norm-minimizing, we must have \( \chi_{\beta}(\partial C) = 0 \). Now alter \( S \) by reversing the orientation of all components of \( \partial C \). The \( \beta \)-norm of \( S \) is unchanged, and both \( S_+ \) and \( S_- \) remain \( \beta' \)-norm-minimizing, since the change in their homology class has trivial norm. Hence it would suffice to prove the claim for the new \( S \).

(c) If some components of \( \partial C \) are in \( S' \) and some in \( S \) then, because \( S_+ \) is \( \beta' \)-taut, \( \chi_{\beta}(\partial C \cap S') \geq \chi_{\beta}(\partial C \cap S) \). Replacing \( \partial C \cap S' \) with \((\partial C \cap S)_- \) does not alter \([S']\) nor raise \( \chi_{\beta}(S') \). Thus it suffices to prove the claim for this altered \( S' \).

To prove the claim, pick a base-point \( x_0 \) on \( \partial M \) and construct \( M - \overline{S} \) a potential function just as in 3.1 (cf. also 3.4 below). Operations (a), (b), and (c) allow one to eliminate components of \( M - \overline{S} \) whose potential is most distant from 0. Eventually all regions can be made to have potential 0 or 1. Moreover each region of potential one is either a collar between a component of \( S \) and a component of \( S' \) (arising from operation (c)) or has oriented boundary completely contained in \( S \) and of trivial \( \chi_{\beta} \), as in (b). Every component of \( \overline{S} \) must lie on the boundary of exactly one region with potential one. So after the operations above, every component of \( S' \) is parallel to a component of \( S \), and each component of \( S \) not parallel to one of \( S' \) has trivial \( \chi_{\beta} \). This proves the claim.

**Proof of Corollary 3.3.** We no longer assume that \( S' \) and \( S \) are disjoint.

Apply 1.3(d) with \( N = \mathcal{N}(\partial S) \) to modify \( S' \) so that for all \( k \geq 0 \), \( \chi_{\beta}(S' \setminus kS) = \chi_{\beta}(S') + k\chi_{\beta}(S) \). From 3.2, there is a \( k \geq 0 \) such that \( S' \setminus kS \subset M' \). Moreover \( S' \setminus kS \) represents \((k + 1)[S] \) in \( H_2(M, \mathcal{N}(\partial S)) \), and so can be decomposed into \( k + 1 \) disjoint pieces, each of them homologous to \( S \) in \( H_2(M, \mathcal{N}(\partial S)) \).
By the above claim, each piece has \( \chi_\beta \geq \chi_\beta(S) \). Hence \( \chi_\beta(S') + k\chi_\beta(S) \geq (k + 1)\chi_\beta(S) \), i.e., \( \chi_\beta(S') \geq \chi_\beta(S) \).

Now consider the notion of "potential" in 3.1 for complements of surfaces in 3-manifolds:

3.4 Definition. For \((T, \partial T) \subset (M, \partial M)\) a surface whose fundamental class is trivial in \(H_2(M, \partial M)\) and \(x_0\) in \(M - T\), define the potential \(\Psi_T : M - T \to \mathbb{Z}\) to be the function which assigns to any \(y\) in \(M - T\) the algebraic intersection with \(T\) of an arc from \(x_0\) to \(y\). The variance \(\psi_T\) of \(T\) is the maximum, over all \(y, z\) in \(M - T\), of \(|\Psi_T(y) - \Psi_T(z)|\) and is independent of \(x_0\).

3.5 Lemma. (a) Suppose \((T', \partial T') \subset (M, \partial M)\) is a surface with \(\partial T' = \partial T\) and \(T'\) is homologous to \(T\) in \(H_2(M, \partial T)\). For \(x_0\) in \(\partial M - \partial T\), \(\Psi_T = \Psi_{T'}\) on \(\partial M - \partial T\). (Note: \(\Psi_T = \Xi_{\partial T}\) perhaps only on the component of \(\partial M\) containing \(x_0\).)

(b) Let \(T'\) be obtained from \(T\) by discarding null-homologous closed components. Then \(\chi_\beta(T') \leq \chi_\beta(T)\) and the variance \(\psi_{T'}\) is achieved on \(\partial M - T'\).

(c) Let \(T\) be a submanifold of \(\partial M\), with all components oriented either consistently or all inconsistently with the orientation of \(\partial M\). If interior \((T)\) is pushed into \(M\), then \(\psi_T = 1\).

Proof. (a) Since \(T\) and \(T'\) are homologous, any path from \(x_0\) to a point \(y\) in \(\partial M - \partial T\) intersects \(T\) algebraically as often as it intersects \(T'\).

(b) If the variance \(\psi_T\) is not achieved on \(\partial M - T\), then either the region of highest or lowest potential in \(M - T\) is disjoint from \(\partial M\). Its boundary must then be a null-homologous closed component of \(T\), which can be removed without increasing \(\chi_\beta(T)\). The result follows by induction.

(c) Let \(x_0\) be a point in \(M - T\) not in the product region between \(T\) and \(\partial M\). Then any other point in \(M - T\) can be reached from \(x_0\) by an arc which crosses \(T\) at most once, and always with the same sign.

3.6. Let \((S, \partial S) \subset (M, \partial M)\) be a \(d\)-surface in a sutured manifold \((M, \gamma)\). Divide \(S\) into two surfaces: \(S_2 = \{\text{components of } S \text{ which } \beta\text{-compress } R(\gamma)\}\), \(S_1 = S - S_2\). Then the decomposition of \(M\) by \(S\) can be factored through the decompositions

\[
(M, \gamma) \xrightarrow{S_1} (M_1, \gamma_1) \xrightarrow{S_2} (M', \gamma').
\]

Theorem. Suppose \((M', \gamma')\) is \(\beta\)-taut. Then either

(a) \(S_2 = \emptyset\) and \((M, \gamma)\) is \(\beta\)-taut,

(b) some component of \(\partial S\) is \(\beta\)-inessential in \(R(\gamma)\), or

(c) every component of \(M_1\) which contains a component of \(S_2\) is a copy of \(D^2 \times S^1\), disjoint from \(\gamma_1\) and \(\beta\), in which \(S_2\) is a collection of coherently oriented meridian disks.
Proof. Case 1. \( S_2 = \emptyset \), so \( S = S_1 \).

An edge of \( \beta \) with both ends in \( R_\pm \) will produce an edge of \( \beta' \) with both ends in \( R'_\pm = R_\pm(\gamma') \). Thus we can assume every edge of \( \beta' \) intersects \( R(\gamma') \) with the same sign.

Next note that if there is a circle in \( R(\gamma) \cap S \) which is inessential in \( R(\gamma) \) or \( S \), then (b) is satisfied. If the circle is in \( R(\gamma) \) it is satisfied directly; if it is in \( S \) this follows from the assumption that \( S_2 = \emptyset \) (\( S \) contains no \( \beta \)-compressing disks for \( R(\gamma) \)).

Claim 1. \( M \) is \( \beta \)-irreducible or (b) is satisfied.

Suppose \( M \) is \( \beta \)-reducible and let \( Q \) be a \( \beta \)-reducing 2-sphere with a minimal number of components of intersection with \( S \). Then an innermost disk \( F \) in \( Q \cap S \) cannot give a \( \beta \)-compression of \( R(\gamma') \), so \( \partial F \subset S \) bounds a disk \( D \) disjoint from \( \beta \) in say \( R'_+ = R_+(\gamma') \). \( D \) cannot lie entirely in \( S \), or \( Q \) would not have a minimal number of components of intersection with \( S \). Hence some part of \( D \) lies in \( R_+ \), and some (including \( \partial D \)) in \( S \). Then an innermost circle of \( S \cap R_+ \) in \( D \) bounds a disk in either \( R_+ \) or \( S \), so (b) is satisfied.

Claim 2. \( R(\gamma) \) and \( S \) are \( \beta \)-incompressible or (b) is satisfied.

We show that \( R_+ \) in \( \beta \)-incompressible. The proof for \( R_- \) and \( S \) is similar.

Let \( Q \) be a \( \beta \)-compressing disk for \( R_+ \) which, among all \( \beta \)-compressing disks, has a minimal number of components of intersection with \( S \).

Subcase 1. \( Q \cap S \) has a circle component.

Then the argument of Claim 1 applies.

Subcase 2. \( Q \) and \( S \) intersect only in arcs.

Then minimality of \( |Q \cap S| \) and Subcase 1 imply that every arc of \( \partial Q - \mathcal{N}(S) \) is \( \beta \)-essential in \( R_+ - \mathcal{N}(S) \) and every arc of \( Q \cap S \) is \( \beta \)-essential in \( S \). Some component \( Q' \) of \( Q - \mathcal{N}(S) \) has its boundary entirely in \( R'_+ \). Since \( R(\gamma') \) is \( \beta' \)-incompressible, \( \partial Q' \) also bounds a disk \( E \) in \( R'_+ = R_+ \approx S \). An outermost arc of \( R_+ \cap S \) in \( E \) cuts off a disk \( F \) lying entirely in \( R_+ \) or entirely in \( S \). But if \( F \) lay entirely in \( R_+ \), it would mean that \( \partial Q - \mathcal{N}(S) \) is not \( \beta \)-essential in \( R_+ - \mathcal{N}(S) \). If \( F \) lay entirely in \( S \), then it would mean that not every arc of \( Q \cap S \) is \( \beta \)-essential in \( S \). Neither is possible, completing the contradiction.

Subcase 3. \( Q \) and \( S \) are disjoint.

Then \( \partial Q \) must bound a disk \( D \) in \( R'_+ - \beta \), but not \( R_+ - \beta \). Then an innermost closed curve of \( S \cap R_+ = \partial S \cap R_+ \) in \( D \) either bounds a disk in \( R_+ - \beta \) or in \( S \) and so satisfies case (b).

Claim 3. \( R(\gamma) \) is \( \beta \)-minimizing or (b) is satisfied.

Suppose \( R_+ \), say, is not \( \beta \)-minimizing in \( H_2(M, \partial R_+) \). Let \( T \) be a \( \beta \)-taut surface with \( [T] = [R_+, \partial R_+] \) in \( H_2(M, \partial R_+) \).

By 3.5(c), \( \psi_{R_+} = 1 \). After discarding null-homologous components of \( T \) (including, by \( \beta \)-irreducibility, all sphere components disjoint from \( \beta \)) we have,
by 3.5(b), \( \psi_T = 1 \). Since \( R_+ \) is \( \beta \)-incompressible, and \( M \) is \( \beta \)-irreducible, any disk component of \( T \) which is disjoint from \( \beta \) is parallel to a component of \( R_+ \). We now proceed with a more delicate version of the proof of 1.3(d).

After possibly performing 2-surgeries to \( T \), we can assume that no simple closed curve of \( S \cap T \) bounds in \( S \) a disk disjoint from \( \beta \). Then since \( R(\gamma') \) is \( \beta \)-incompressible, either there is a component of \( \partial S \) bounding a disk in \( R(\gamma) \) (case (b)) or no simple closed curve of \( S \cap T \) bounds in \( T \) a disk disjoint from \( \beta \). Hence any sphere component of \( S \setminus T \) either lies entirely in \( S \), entirely in \( T \) or intersects \( \beta \) in at least two points.

Similarly, we may assume that any sphere component of \( R'_+ \) either lies in \( S \), lies in \( R_+ \), or intersects \( \beta \) in at least two points.

Since \( \partial T = \partial R_+ \), \( \partial (S \setminus T) = \partial (R'_+) \). Since \( \psi_T = 1 \), we can assume that the variance of \( \Lambda = S \cap T \) in \( S \) is also 1. Then by Lemma 3.2(b), \( S \setminus T \) can be isotoped into \( M' \).

Since \( R'_+ \) is \( \beta \)-incompressible, if any component of \( \partial (S \setminus T) \) bounds a disk in \( M \) disjoint from \( \beta \), it bounds such a disk in \( R'_+ \). Since \( T \) is taut, if a component of \( \partial T = \partial R_+ \) bounds a disk in \( M \), it bounds a disk in \( T \).

Letting

\[ e = |\text{spheres of } S \setminus T \text{ intersecting } \beta \text{ in a single point}|, \]
\[ e' = |\text{spheres of } R'_+ \text{ intersecting } \beta \text{ in a single point}|, \]
\[ d = |\text{disks in } S \setminus T \text{ disjoint from } \beta|, \]
\[ d'_\gamma = |\text{disks in } R'_+ \text{ disjoint from } \beta|, \]
\[ d_S = |\text{disks in } S \text{ disjoint from } \beta|, \]
\[ d_T = |\text{disks in } T \text{ disjoint from } \beta|, \]
\[ d_\gamma = |\text{disks in } R_+ \text{ disjoint from } \beta|, \]
we thereby derive \( d \leq d'_\gamma, d \gamma \leq d_T, e = |\text{spheres of } S \text{ intersecting } \beta \text{ in a single point}| + |\text{spheres of } T \text{ intersecting } \beta \text{ in a single point}| \), and similarly for \( e' \) and spheres of \( S \) and \( R_+ \).

Then

\[
\chi_\beta(S \setminus T) = |(S \setminus T) \cap \beta| - \chi(S \setminus T) + d + e = |S \cap \beta| + |T \cap \beta| - \chi(S) - \chi(T) + d + e = \chi_\beta(S) + \chi_\beta(T) + d - d_S - d_T.
\]

Since \( \chi_\beta(T) < \chi_\beta(R_+) \),

\[
\chi_\beta(S \setminus T) < \chi_\beta(S) + \chi_\beta(R_+) + d'_\gamma - d_S - d_\gamma = |S \cap \beta| + |R_+ \cap \beta| - \chi(S) - \chi(R_+) + d'_\gamma + e' = \chi_\beta(R'_+).
\]

Thus \( S \setminus T \subset M' \) contradicts the \( \beta \)-tautness of \( R'_+ \).

**Case 2.** \( S_2 \neq \emptyset \) (so \( (M, \gamma) \) is not taut).

With no loss of generality assume every component of \( M_1 \) contains a component of \( S_2 \). Every component \( D \) of \( S_2 \) produces two disks in \( M' \), one of them, denoted \( D_s \), is bounded by a suture and the other, denoted \( D_n \), is not. Construct an imbedded directed graph \( X \) in \( M_1 \) by choosing a vertex in every component of \( M' \), choosing an edge through each component of \( D \) with ends on the vertices in the components of \( M' \) on which \( D_s \) and \( D_n \) lie. Orient the edge to point in the direction from \( D_n \) to \( D_s \).

\[ \text{FIGURE 3.3} \]

**Claim 1.** No component of \( M' \) has more than one edge directed in. If an edge is directed into a compact \( \bar{M} \) of \( M' \), then \( \bar{M} \) is a 3-ball disjoint from \( \beta \) and has at least one edge pointing out.

**Proof of Claim 1.** \( D_s \) is a disk in \( \partial M_2 \) disjoint from \( \beta \) and bounded by a suture. Since \( \partial M_2 - \gamma \) is \( \beta \)-incompressible, the other component of \( \partial M_2 - \gamma \) adjacent to that suture must also be a disk \( D' \) disjoint from \( \beta \). Hence \( \partial \bar{M} \) is
a sphere disjoint from $\beta$ and any other suture. By $\beta$-irreducibility of $M'$, $\overline{M}$ is a 3-ball disjoint from $\beta$.

If $D'$ lies entirely in $\partial M$, then (b) is satisfied. In general, an innermost simple closed curve of $\partial S$ lying in $D'$ either bounds a disk in $\partial M$ (case (b)) or bounds a disk $D''$ in $S$. Either $\partial D''$ bounds a disk in $\partial M$ (again case (b)) or it is a compressing disk for $\partial M$ and so a component of $S_2$. Then an edge of $X$ points out through $D''$.

**Claim 2.** $X$ is a disjoint union of cycles.

Suppose there are $n$ vertices of $X$. Since every component of $M_1$ contains some disk in $S_2$, no vertex is isolated. By Claim 1, there is at least one edge pointing out of each vertex, and at most one pointing in. Hence there are exactly $n$ edges in $X$, so $X$ is the union of cycles.

By Claim 2, every vertex of $X$ has an edge pointing in, so, by Claim 1, each component of $M'$ is a 3-ball. Hence $M_1$ deformation retracts to $X$, completing Case 2.

**3.7 Definition.** For $S$ a $d$-surface in a sutured manifold $(M, \gamma)$, let $S_{k,l}$ denote $S \wedge kR_+ \wedge lR_-$.

**3.8 Corollary.** If $(M, \gamma) \xrightarrow{S} (M', \gamma')$ is a $\beta$-taut sutured manifold decomposition and no component of $\partial S$ bounds a disk in $R(\gamma) - \beta$, then $(M, \gamma) \xrightarrow{S_{k,l}} (M'', \gamma'')$ is a $\beta$-taut sutured manifold decomposition.

**Proof.** With no loss of generality it suffices to consider the case $k = 1, l = 0$. Since $(M, \gamma)$ is $\beta$-taut, no component of $S$ is a $\beta$-compressing disk for $R(\gamma)$, hence no component of $S$ is a disk disjoint from $\beta$ with $\partial S$ in $R(\gamma)$. There is a sutured manifold decomposition $(M'', \gamma'') \xrightarrow{T} (M', \gamma')$ in which $T$ is disjoint from $\beta$ and consists of product disks and annuli. A cross-section of $T$ is shown in Figure 3.4.

We wish to show that no component of $\partial T$ bounds a disk in $R(\gamma'') - \beta$ so that 3.6 applies. The complement of $\partial T$ in $R_+''$ is naturally homeomorphic to the union of $R_+ \wedge S$ and of the complement of $\partial S$ in $R_+$, with $\partial T$ corresponding in both cases to $\partial S \cap R_+$.

A disk in $R_+ \wedge S - \beta$ with boundary in $\partial S \cap R_+$ would contain a disk with boundary in $R_+ \cap S$ and interior entirely contained in $R_+ - \beta$ interior entirely contained in $S - \beta$. The first is impossible by hypothesis, and the second is also because $(M, \gamma)$ is $\beta$-incompressible.

By hypothesis no component of $\partial T$ can bound a disk in $R_+$.

**3.9 Corollary.** Suppose

$$(M_0, \gamma_0) \xrightarrow{S_1} (M_1, \gamma_1) \xrightarrow{S_2} \ldots \xrightarrow{S_n} (M_n, \gamma_n)$$

is a sequence of sutured manifold decompositions in which
(a) no component of $M_0$ is a solid torus disjoint from $\beta$ and $\gamma_0$,
(b) each $S_i$ is either a conditioned surface, a disk disjoint from $\beta$ intersecting $A(\gamma_{i-1})$ twice, or an annulus disjoint from $\beta$ with at least one boundary component $\beta$-essential in $R_{\pm}(\gamma_{i-1})$, and the other boundary component lying in $R_{\mp}(\gamma_{i-1})$,
(c) no closed component of any $S_i$ separates.

Then if $(M_n, \gamma_n)$ is $\beta$-taut, so is every decomposition in the series.

Proof. The result follows from 3.6(a) once we verify that neither 3.6(b) nor 3.6(c) occurs anywhere in the sequence.

Suppose some decomposition $(M_{i-1}, \gamma_{i-1}) \xrightarrow{S_i} (M_i, \gamma_i)$ can be factored as in 3.6(c). That is, there is a collection of components $\tilde{S}$ in $S_i$ so that the decomposition $(M_{i-1}, \gamma_{i-1}) \xrightarrow{\tilde{S}} (\tilde{M}, \tilde{\gamma})$ yields a component $M'$ of $\tilde{M}$ which is a solid torus disjoint from $\beta_i$ and with boundary in $R_+(\tilde{\gamma})$, say. Take, in fact,
$S_i$ to be the first surface in the sequence admitting this factorization. Then there are three possibilities for $\partial M' \subset R_+ (\gamma_{i-1}) \approx \hat{S}$:

(i) $\partial M'$ is a component of $\hat{S}$. This would contradict hypothesis (c).

(ii) $\partial M'$ is a component of $R_+ (\gamma_{i-1})$. Then, since $S_i$ was the first surface in the decomposition to admit such a factorization, in fact $M'$ is a component of $M_0$, contradicting hypothesis (a).

(iii) $\partial M' - \hat{S}$ is a null-homology in $R_+ (\gamma_{i-1})$ of $\partial \hat{S}$. This would contradict hypothesis (b) or 2.4(b).

Suppose 3.6(b) occurs and let $S_i$ be its last occurrence. Then 3.6 applied to each term in the series

\[(M_i, \gamma_i) \xrightarrow{S_{i+1}} (M_{i+1}, \gamma_{i+1}) \cdots \xrightarrow{S_n} (M_n, \gamma_n)\]

shows that $(M_i, \gamma_i)$ is $\beta$-taut. By hypothesis 3.9(b), $S_i$ is an annulus disjoint from $\beta$ with one end $\beta$-inessential in $R_+$, say, and the other end $\beta$-essential in $R_-$. There is a suture of $\gamma_i$ at each end of $S_i$: $\gamma_+$ on the positive side $S_i^+$ and $\gamma_-$ on the negative side $S_i^-$. Since the end of $S_i$ in $R_+$ bounds a disk disjoint from $\beta$, $\gamma_+$ bounds a disk in $R_+ (\gamma_i)$. Since $(M_i, \gamma_i)$ is $\beta$-taut, $\gamma_+$ must bound a disk disjoint from $\beta$ in $R_- (\gamma_i)$. This disk cannot contain $S_i^-$ since it has the suture $\gamma_-$ at an end. Hence the disk lies in $R (\gamma_{i-1})$, a contradiction.

4. Complexity: Sutured manifold hierarchies

The goal of this section is to show that for any $\beta$-taut sutured manifold there is a finite sequence of $\beta$-taut decompositions which terminates in a manifold with trivial $H_2(M, \partial M)$. Let $M_\beta$ denote $M - \mathcal{N}(\beta)$.

4.1 Definition. An annulus $(S^1 \times I; S^1 \times \{0\}, S^1 \times \{1\}) \subset (M_\beta; R_+ (\gamma), R_- (\gamma))$ in the sutured manifold $(M, \gamma, \beta)$ is called a product annulus, and a disk $(I \times I; I \times \{0\}, I \times \{1\}, \partial I \times I) \subset (M_\beta; R_+ (\gamma), R_- (\gamma), A(\gamma))$ is called a product disk. A product annulus is trivial if it extends to an imbedding $(D^2 \times I; D^2 \times \{0\}, D^2 \times \{1\}) \subset (M_\beta; R_+ (\gamma), R_- (\gamma))$.

A disk $(I \times I; I \times \{0\}, I \times \{1\}, \partial I \times I) \subset (M_\beta; R_+ (\gamma), R_- (\gamma), \mathcal{N}(\beta))$ is called an amalgamating disk because one can view the disk as amalgamating the two (or possibly one) arcs of $\beta$ to which $\partial I \times I$ runs parallel. If both components of $\partial I \times I$ lie on the same component $\beta_0$ of $\beta$, the disk is a self-amalgamating disk at $\beta_0$.

A disk $(I \times I; I \times \{0\}, I \times \{1\}, \{0\} \times I, \{1\} \times I) \subset (M_\beta; R_+ (\gamma), R_- (\gamma), \mathcal{N}(\beta), A(\gamma))$ is called a cancelling disk because one can view the disk as pushing the arc of $\beta$ along which $\{0\} \times I$ runs into the structure along which $\{1\} \times I$ runs.
4.2 Lemma. Suppose $(M, \gamma) \to (M', \gamma')$ is a sutured manifold decomposition with $J$ either a product disk or product annulus. Suppose further that each component of $\partial J$ is $\beta$-essential in $R(\gamma)$. Then $(M, \gamma, \beta)$ is $\beta$-taut if and only if $(M', \gamma', \beta)$ is $\beta$-taut.

Proof. "If" follows from 3.6. So suppose $(M, \gamma)$ is $\beta$-taut. $R(\gamma')$ is naturally homeomorphic to $R(\gamma) - \partial J$, so $\chi_\beta(R(\gamma')) = \chi_\beta(R(\gamma))$ or $\chi_\beta(R(\gamma)) - 2$ depending on whether $J$ is a product annulus or a product disk. If $R(\gamma')$ is not $\beta$-minimizing, then attaching $\partial J \cap R(\gamma)$ to a $\beta$-minimizing surface would produce a surface homologous to $R(\gamma)$, with the same boundary, but lower $\beta$-norm. Hence $R(\gamma')$ is $\beta$-minimizing.

It is easy to check that $R'_\pm = R_\pm(\gamma')$ is $\beta$-minimizing. Since $M$ is $\beta$-irreducible, so is $M' = M - J$.

Suppose $Q$ is a $\beta$-compressing disk for $R(\gamma')$. Since $R(\gamma')$ can be regarded as $R(\gamma) - \partial J$, we can take $\partial Q \subset R(\gamma)$. Since $R(\gamma)$ is $\beta$-incompressible, $\partial Q$ bounds a disk in $R(\gamma)$ disjoint from $\beta$. Since $\partial J$ is $\beta$-essential in $R(\gamma)$, that disk persists in $R'_\pm \cong R_\pm - \partial J$, contradicting the fact that $Q$ is a $\beta$-compressing disk.

4.3 Lemma. Suppose $(M, \gamma)$ is a $\beta$-taut sutured manifold, $Q$ is a cancelling disk for the arc component $\beta_0$ of $\beta$, and $\beta_- = \beta - \beta_0$. Then $(M, \gamma)$ is also $\beta_-$-taut.

Proof. Claim 1. $M$ is $\beta_-$-irreducible.

Proof of Claim 1. Suppose not. Among all spheres disjoint from $\beta_-$, not bounding balls disjoint from $\beta_-$ and put in general position with respect to $Q$, let $S$ have minimal number of components of intersection with $Q$. No component of $S \cap Q$ is a simple closed curve, for otherwise we could produce such a sphere with fewer components of intersection with $Q$ by splitting $S$ along an innermost disk of $Q - S$. If $S \cap Q \not= \emptyset$, then let $\alpha$ be an outermost arc in $Q$ and $F$ be a disk in $Q - S$ whose boundary consists of the union of $\alpha$ and a subarc of $\beta_0$. Then there is a regular neighborhood of $F$ whose boundary $S_0$ intersects $S$ in a regular neighborhood $N$ of $\alpha$. If we split $S$ along $S_0 - N$, the result is two spheres: $S_0$ and a sphere $S_1$ which intersects $Q$ in fewer components than does $S$. Hence $S_1$ bounds a ball disjoint from $\beta_-$. Since $F$ is disjoint from $\beta_-$, $S_0$ also bounds a ball disjoint from $\beta_-$, and finally so must $S$, a contradiction.

Claim 2. $R(\gamma)$ is $\beta_-$-incompressible.

Proof of Claim 2. Suppose not, and among all $\beta_-$-compressing disks for $R(\gamma)$, put in general position with respect to $Q$, let $D$ have minimal number of components of intersections with $Q$. Then an argument quite similar to that of Claim 1, using also the $\beta_-$-irreducibility of $M$, leads to a similar contradiction.

Claim 3. $R(\gamma)$ is $\beta_-$-minimizing.
Proof of Claim 3. Let $S$ be a $\beta_-$-taut surface in $M$, with $\partial S = \gamma$ homologous to $R_\pm$ rel $\gamma$ and, among all such, having minimal number of components of intersection with $Q$. Since $S$ is $\beta_-$-incompressible and $M$ is $\beta_-$-irreducible, there are no simple closed curves in $S \cap Q$. Since $S$ is $\beta_-$-minimizing, there are no arcs of $S \cap Q$ with both ends in $\beta \subset \partial Q$. Since $\partial S = \gamma$, $\partial S \cap \partial Q$ is a single point, lying in $A(\gamma_0)$. Hence $S \cap Q$ consists of a single arc with one end in $\partial Q \cap A(\gamma_0)$ and one end in $\beta$. But then $\chi_{\beta_-}(S) = \chi_\beta(S)-1 = \chi_\beta(R_\pm)-1 = \chi_{\beta_-}(R_\pm)$, so $R_\pm$ are also $\beta_-$-minimizing.

4.4 Lemma. Suppose $(M, \gamma)$ is a $\beta$-taut sutured manifold, and $Q$ is an amalgamating disk for distinct arc components $\beta_0$ and $\beta_1$ of $\beta$. Let $\beta_- = \beta - \beta_0$. Then $(M, \gamma)$ is also $\beta_-$-taut.

Proof. The proof is essentially the same as that of 4.3 above.

4.5 Lemma. Suppose $(M, \gamma)$ is a $\beta$-taut sutured manifold, and $Q$ is a self-amalgamating disk at $\beta_0 \subset \beta$. Suppose the two arc components of $\partial Q \cap R(\gamma)$ are $\beta$-essential in $R(\gamma)$. Let $\beta_- = \beta - \beta_0$, and $(M', \gamma')$ be the sutured manifold obtained by decomposing $(M, \gamma, \beta_-)$ along the product annulus in $Q \cup \mathcal{A}(\beta_0)$. Then $(M', \gamma')$ is $\beta_-$-taut.

Proof. This is a combination of 4.2 and 4.3.

4.6 Definition. Let $(D^2, \partial D^2) \subset (M_\beta, \partial M_\beta)$ be a disk in the sutured manifold $(M, \gamma, \beta)$. A circuit around $\partial D^2$ will pass $\mu$ times across neighborhoods of edges of $\beta$, $\varphi$ times across neighborhoods of vertices of $\beta$, and $\nu$ times across components of $A(\gamma)$. Define the index

$$I(D) = \mu + \nu + 3\varphi - 2.$$
If \( \partial D^2 \) lies entirely in a neighborhood of a vertex or is a meridian circle of \( \mathcal{N}(\beta) \) set \( I(D) = 1 \), and if \( \partial D^2 \) lies entirely in \( R(\gamma) \) set \( I(D) = -2 \).

**Remark.** If \( I(D) < 0 \), then either \( \partial D^2 \subset R(\gamma) \) or some edge of \( \beta \) has both ends in \( R_+ \) or both ends in \( R_- \) (and \( D \) compresses the edge into \( R(\gamma) \)).

If \( I(D) = 0 \), then \( D \) is either a cancelling, amalgamating or product disk, depending on whether \((\mu, \nu) = (2, 0), (0, 2) \) or \((1, 1) \).

4.7 Definition. For a collection \( \{F\} \) of index-zero disks in \( M_\beta \), the combination of decomposition along product disks and annuli \((M, \gamma, \beta) \to (M', \gamma', \beta) \) with cancellation and amalgamation of arcs in \( \beta \) to produce a complex \( \beta' \) in \( M' \) is called elimination of \( \{F\} \). As in Lemma 4.5 we view elimination of a self-amalgamating disk as the combination of a decomposition along a product annulus with a cancellation.

4.8 Lemma. Suppose \((M, \gamma) \xrightarrow{S} (M', \gamma') \) is a sutured manifold decomposition, and \((D, \partial D) \subset (M_\beta, \partial M_\beta) \) is a disk intersecting \( S \) only in arcs. Let \( D_1, \cdots, D_n \) be the components of \( D - S \), regarded as disks in the manifold \( M'_\beta - S \). Then

\[
I(D_1) + \cdots + I(D_n) = I(D).
\]

**Proof.** We need not consider the case in which \( \partial D \) lies entirely in the neighborhood of a vertex or is a meridian circle of \( \mathcal{N}(\beta) \), for then \( D \) and \( S \) are disjoint.

It suffices to consider the case in which \( S \cap D \) is a single arc \( \alpha \). The number of vertices crossed by \( \partial D_1 \cup \partial D_2 \) is clearly the same as for \( \partial D \), since \( S \), and hence \( \alpha \), are disjoint from the vertices of \( \beta \). Then \( \gamma' \) of 4.3 is unchanged. If an end of \( \alpha \) lies in \( \beta \), then \( \mu \) for \( D_1 \cup D_2 \) is 1 greater than \( \mu \) for \( D \). If an end of \( \alpha \) lies in \( A(\gamma), T(\gamma), \) or \( R_+ \) (hence in general in \( \partial M \)), then one side or the other of the component of \( \partial S \) in which \( \alpha \) terminates becomes a suture of \( \gamma' \). Hence \( \nu \) for \( D_1 \cup D_2 \) is 1 greater than \( \nu \) for \( D \). Thus in general \( \mu + \nu \) for \( D_1 \cup D_2 \) is 2 greater than \( \mu + \nu \) for \( D \). But since the former contains two disks, the total index remains unchanged.

4.9 Definition. For \( M_\beta \)-irreducible, a finite collection of disjoint \( \partial \)-reducing disks \( \{\{D_i\}, \{E_j\}\} \) in the irreducible 3-manifold \( M_\beta \) is called a set of **complexity disks** if

(a) \( M_\beta - (\bigcup \mathcal{N}(D_i)) \) is the disjoint union of \( m \) manifolds \( \{P_\lambda\} \) of the form (closed surface) \( \times I \), \( k \) \( \partial \)-irreducible manifolds \( \{M_\kappa\} \) not of that form, and \( l \) handlebodies \( \{H_\lambda\} \),

(b) \( \bigcup E_j \subset (\bigcup H_\lambda) \),

(c) each component of \( (\bigcup H_\lambda) - (\bigcup \mathcal{N}(E_j)) \) is a 3-ball whose boundary intersects closure\( ((\bigcup \mathcal{N}(E_j)) \cup (\bigcup \mathcal{N}(D_i))) \) in \( \leq 3 \) disks.
Let $d_\kappa$ (resp. $d'_\mu$) denote the number of disks $\{D_i\}$ which lie in $\partial M_\kappa$ (resp. $\partial P_\mu$).

Recall that the length (cf. [9, IV.13]) of a Haken manifold is the length of the longest partial hierarchy which can be constructed using only surfaces which are incompressible, boundary incompressible, but not disks.

4.10 Definition. For $(M, \gamma, \beta)$ a connected $\beta$-irreducible sutured manifold and $([D_i], \{E_j\})$ a set of complexity disks, define the complexity $C(M, \{D_i\}, \{E_j\})$ of $(M, \{D_i\}, \{E_j\})$ to be the ordered 5-tuple $(C_1, C_2, C_3, C_4, C_5)$ where

$$C_1 = \sum \text{(length } M_\kappa), \quad C_2 = \sum \{I(D_i)^2 | I(D_i) \geq 0\},$$

$$C_3 = \sum_{1 \leq \kappa \leq k} d_\kappa, \quad C_4 = m + \sum_{1 \leq \mu \leq m} (d'_\mu)^2,$$

$$C_5 = \{I(D_i) > 0\} \cup \{I(E_j) > 0\} \text{ (repetitions retained).}$$

4.11 Definition. For $(M, \gamma, \beta)$ a connected sutured manifold define the complexity $C(M, \gamma, \beta)$ to be the minimum of the complexity of $(M, \{D_i\}, \{E_j\})$ taken over all sets $([D_i], \{E_j\})$ of complexity disks. The order is the dictionary order, with the order on the finite sets of integers $C_5$ given as follows (see [3, 4.3]): If $A$ and $B$ are two finite sets of integers, first order the elements of $A$ and the elements of $B$ in descending order, then compare $A$ to $B$ lexicographically.

For example, suppose the set $B$ is obtained from $A$ by replacing any positive element $\{a\}$ of $A$ by the set $\{b_1, c_1, b_2, c_2, \ldots, b_n, c_n\}$ where each of $b_i$ and $c_i$ is positive and always $b_i + c_i = a$. Then under this ordering, no matter how large $n$ is, always $B < A$.

4.12 Definition. For $\{F\}$ a set of disjoint index-zero disks in $M_\beta$, define $\hat{C}(\{F\})$ to be the complexity of the connected sutured manifold obtained by eliminating $\{F\}$ (cf. 4.7), but with $C_5$ altered to

$$C_5 = \{I(D_i) \geq 0\} \cup \{I(E_j) \geq 0\}.$$

Define the reduced complexity $\hat{C}(M, \gamma)$ to be the minimum of $\hat{C}(\{F\})$ taken over all sets $\{f\}$ of disjoint index-zero disks.

4.13 Remarks. (a) In fact in 4.12 we need only consider sets $\{F\}$ in which no disk is $\partial$-parallel, and no two disks are parallel in $M_\beta$. For example, if a disk $D$ is boundary parallel in $M_\beta$, then a set of complexity disks for $M - D$ is a set of complexity disks for $M$.

(b) $\hat{C}(M, \gamma) \leq C(M, \gamma)$. Indeed, eliminating any set of index-zero disks never increases complexity, so we may assume that in the calculation of $\hat{C}(M, \gamma)$ all index-zero disks have been eliminated ($C_5' = C_5$).
(c) If $M$ is $\beta$-taut, then all complexity disks have nonnegative index. In particular, if $fC(M) = (0,0,0,0,\emptyset)$ then, after eliminating index zero disks, $M_\beta$ becomes a handlebody ($C_1 = C_4 = 0$) admitting an empty set of complexity disks ($C'_5 = \emptyset$). Thus $M$ is a union of 3-balls and $\beta = \emptyset$.

4.14 Definition. For $(M, \gamma, \beta)$ a sutured manifold and $(S, \partial S) \subset (M, \partial M)$ a $d$-surface, a good disk for $S$ is a disk $D$ disjoint from $\beta$ with $D \cap (S \cup \partial M) = \partial D$ the union of an arc in $S$ and an arc in $R_4$, and $I(D) \leq 0$, where index is computed in the manifold $M_S$ obtained by decomposing $M$ along $S$.

Remark. Seven examples of good disks are shown in [3, Figure 4.2].

4.15 Lemma. Suppose $(M, \gamma)$ is a sutured manifold, $(S, \partial S) \subset (M, \partial M)$ is a surface, and $S'$ is $S$ after a 2-surgery along a good disk. Let $(M_S, \gamma_S)$ and $(M_{S'}, \gamma_{S'})$ be the sutured manifolds obtained by decomposing along $S$ and $S'$ respectively. Then:

(a) $(M_{S'}, \gamma_{S'})$ is obtained from $(M_S, \gamma_S)$ by either $\beta$-compressing $R(\gamma_S)$ or decomposing it along a product disk;

(b) if $S$ gives a $\beta$-taut sutured manifold decomposition, so does $S'$.

Proof. (a) If $I(D) = -2$ then the former holds; if $I(D) = 0$ the latter holds.

(b) follows from (a) and 4.2.

4.16 Lemma. Suppose $(S, \partial S) \subset (M, \partial M)$ is incompressible, and $S'$ is obtained from $S$ by 2-surgery along a disk whose boundary is the union of an arc in $S$ and an arc of $\partial M$. If $S'$ is $\partial$-parallel, so is $S$.

Proof. Dually, $S$ is obtained from $S'$ by 1-surgery along an arc $\alpha$ in $\partial M$ with $\partial \alpha \subset \partial S'$. (The 1-surgery looks like a "blistering" of $\partial M$ near $\alpha$.) If $\alpha$ lay inside the submanifold $T$ of $\partial M$ to which $S'$ is parallel, then the disk $\alpha \times I$ in the product region between $T$ and $S'$ would be a compressing disk for $S$.

Hence $\alpha$ lies outside $T$. Then the product structure between $S$ and $T$ extends to a product structure between $S'$ and $T \cup$ (neighborhood of $\alpha$).

4.17 Theorem. Suppose $(M, \gamma)$ is a connected $\beta$-taut sutured manifold for which $M_\beta$ has no index-zero $\beta$-compressing disks, $(S, \partial S) \subset (M, \partial M)$ is a connected $\beta$-incompressible surface, and the sutured manifold obtained by decomposing along $S$ is $\beta$-taut. Let $(M_S, \gamma_S)$ be any of its components. Then $C(M_S, \gamma_S) \leq \hat{C}(M, \gamma) = C(M, \gamma)$ and either

(a) $S - \mathcal{N}(\beta)$ is $\partial$-parallel in $M_\beta$ and $[S, \partial S]$ is trivial in $H_2(M, \partial M)$, or

(b) $\hat{C}(M_S, \gamma_S) < \hat{C}(M, \gamma)$.

Proof. Let $S_\beta$ denote $S - \mathcal{N}(\beta)$. Choose a collection $\{\{D_i\}, \{E_j\}\}$ of complexity disks in $M_\beta$, which realize the complexity of $(M, \gamma)$, and let $\{M_\kappa\}$ and $\{H_\lambda\}$ be as in 4.9(a). Modify $S_\beta$ as follows:
(a) Using $\beta$-irreducibility of $M$ and $\beta$-incompressibility of $S$, isotope $S_\beta$ to remove circles of intersection with complexity disks.

(b) Suppose there is an arc $\alpha \subset \beta$ such that $\alpha$ has one end in $R(\gamma)$, one end in $S_\beta$, and interior disjoint from $S_\beta$. Replace the meridian disk $\mathcal{N}(\alpha) \cap S$ by the annulus $\mathcal{N}(\alpha)$. This alteration affects neither parallelism with $\partial M_\beta$, nor the $\beta$-tautness or reduced complexity of $M_S$.

(c) Suppose in a complexity disk $\Delta$ there is an outermost arc of $S_\beta \cap \Delta$, which cuts off a good disk in $\Delta$. Then do 2-surgery on $S_\beta$ via this good disk. By 4.15(a), this does not change $\check{C}(M_S, \gamma_S)$ and, by Lemma 4.16, cannot make $S_\beta \partial$-parallel unless it was originally.

After enough such modifications, any outermost arc of intersection with $S_\beta$ in any complexity disk has positive index, for operation (b) changes cancelling and amalgamating disks into product disks, and operation (c) eliminates product disks cut off by outermost arcs.

**Case 1.** For some $M_\kappa$, $S_\beta \cap M_\kappa$ has a component which is not boundary parallel. Then $M_\kappa - S_\beta$ has length $< \text{length } M_\kappa$. This reduces $C_1$.

Henceforth then assume

A. For each $M_\kappa$, every component of $M_\kappa \cap S_\beta$ is boundary parallel.

Then each $M_\kappa - S_\beta$ is a union of handlebodies or (closed surfaces) $\times I$ and a copy of $M_\kappa$. Each $P_\mu - S_\beta$ is a union of handlebodies and (possibly) copies of $P_\mu$. Each $H_\lambda - S_\beta$ is a union of handlebodies. In particular, the collection
\{D'\} of all components of \(\{D_i - S_\beta\}\) can be extended to a set of complexity disks \(\{(D'), \{E'\}\}\) for \(M - S\).

**Case 2.** For some disk \(D_i\), \(S_\beta \cap D_i \neq \emptyset\).

Since at least two disks of \(D_i - S_\beta\) have positive index, it follows from 2.2 that a sutured decomposition along \(S\) reduces \(C_2\) without increasing \(C_1\).

Henceforth we therefore also assume

B. For every disk \(D_i\), \(S_\beta \cap D_i = \emptyset\).

**Case 3.** \(S\) is contained in some \(M_\kappa\).

By assumption A, \(S_\beta\) is boundary parallel in \(M_\kappa\). If, in fact, \(S_\beta\) is boundary parallel in \(M_\beta\), then one component of \(M_\beta - S_\beta\) is unchanged, and the other is either a (closed surface) \(\times I\) or a handlebody, hence has lower complexity.

If \(S_\beta\) is not boundary parallel in \(M_\beta\), the piece of the boundary of \(M_\kappa\) to which \(S_\beta\) is parallel must contain a \(D_i\). Then decomposing along \(S_\beta\) does not increase \(C_1\) and \(C_2\) but reduces \(C_3\).

We therefore assume

C. \(S_\beta\) and \((\bigcup M_\kappa)\) are disjoint.

Then decomposing along \(S\) cannot increase \(C_1\), \(C_2\), or \(C_3\).

Recall that an incompressible, \(\partial\)-incompressible surface in a handlebody or in (surface) \(\times I\) either is closed and \(\partial\)-parallel or decomposes the 3-manifold into handlebodies.

**Case 4.** \(S\) is contained in some \(P_\mu\).

If \(S_\beta\) is boundary parallel in \(M_\beta\) then, as in Case 3, the complexity of neither component of \(M_\beta - S_\beta\) is larger than that of \(M_\beta\).

If \(S_\beta\) is closed and boundary parallel in \(P_\mu\) but not in \(M_\beta\) then, of the terms of \(C_4\), \(m\) is increased by one, but \(d'_\mu\) is partitioned into two positive integers, the sum of whose squares then must be no larger than \((d'_\mu)^2 - 2\). Hence \(C_4\) is reduced.

If \(S_\beta\) has boundary, then \(m\) does not increase, but \(\sum d'_\mu^2\) decreases and again \(C_4\) is reduced.

We therefore assume

D. \(S_\beta\) is contained in some \(H_\lambda\).

**Case 5.** \(S_\beta\) intersects some \(E_i\).

\(H_\lambda - S_\beta\) is a union of handlebodies, so \(C_1, C_2, C_3, C_4\) are unchanged. We now consider \(C'_5\). Let \(\{E_\sigma\}\) denote the subcollection of \(\{E_j\}\) which intersects \(S_\beta\), and \(\{E_\tau\}\) the subcollection which does not.

**Claim.** There is an isotopy of \(S_\beta\) rel \(\gamma\) and a collection of disks \(\{E'_\sigma\}\), each parallel to some \(E_\sigma\), such that, for \(\{E'\}\) the set of disks in \(M - S_\beta\) obtained by splitting \(\{E'_\sigma\}\) along \(S_\beta\), \((\{D_i\}, \{E_\tau\} \cup \{E'\})\), is a set of complexity disks for \(M - S\).
Proof of Claim. By general position, $S_{\beta}$ may be isotoped so that, outside $\mathcal{N}(\bigcup E_{\sigma})$, each component of $H_{\lambda} - S$ is a 3-ball whose closure intersects $\mathcal{N}(\bigcup E_{\sigma})$ in $\leq 3$ disks (see [3, Figure 4.4]). Isotope $S_{\beta}$ in $\mathcal{N}(\bigcup E_{\sigma}) = (\bigcup E_{\sigma}) \times I$ so that at most a single saddle occurs between distinct levels $0 = \alpha_1 < \cdots < \alpha_n = 1$. Then $\{E_{\sigma}'\} = \{E_{\sigma}\} \times \{\alpha_i\}$ satisfies the claim (see [3, Figure 4.1]).

To understand the effect on $C_5'$, consider a single $E_{\sigma}$. Each copy $E_{\sigma} \times \alpha_j$ is broken into disks by $S_{\beta}$, and at least two disks have positive index, since there are no good disks for $S_{\beta}$. From 4.8 the corresponding integers in $C_5'(M - S)$ are all strictly smaller than the entry $I(E_{\sigma})$ in $C_5'(M)$, so $C_5'$ is decreased.

Case 6. $S_{\beta}$ is disjoint from $\{E_i\}$.

Then $S_{\beta}$ is parallel to a complexity disk. Obtain a set of complexity disks for $M - S$ by removing from $\{(D_i), \{E_j\}\}$ all those disks parallel to components of $S_{\beta}$. This does not increase $C_1, \cdots, C_4$, but reduces $C_5'$.

Finally $S_{\beta}$ parallel in $M_{\beta}$ implies that $S$ has trivial fundamental class in $H_2(M_{\beta}, \partial M_{\beta}) \cong H_2(M, \partial M) \cup \mathcal{N}(\beta))$. The exact sequence of the triple $(M, \partial M \cup \mathcal{N}(\beta), \partial M)$ then implies $[S, \partial S]$ is trivial in $H_2(M, \partial M)$.

4.18 Definition. A $\beta$-taut sutured manifold hierarchy is a finite sequence

$$(M_0, \gamma_0), S_1 \rightarrow (M_1, \gamma_1), S_2 \rightarrow \cdots \rightarrow S_n \rightarrow (M_n, \gamma_n)$$

of $\beta$-taut sutured manifold decompositions for which

(a) each $S_i$ is either a conditioned surface, a product disk, or a $\beta$-nontrivial product annulus,

(b) no closed component of any $S_i$ separates,

(c) if either end of a product annulus

$$(S^1 \times I, S^1 \times 0, S^1 \times 1) \subset (M_i, R_+(\gamma_i), R_-(\gamma_i))$$
in $S_{i+1}$ bounds a disk in $R(\gamma_i)$, then no component of $\beta$ incident to the disk is an edge parallel to the annulus,

(d) $H_2(M_n, \partial M_n) = 0$, so in fact $\partial M_n$ is a union of spheres. (Note, however, that because bits of $\beta$ may lie in $M_n$, $\beta$-irreducibility of $M$ is not enough to conclude here that $M_n$ is a union of 3-balls.)

4.19 Theorem. Any $\beta$-taut sutured manifold $(M_0, \gamma_0)$ admits a $\beta$-taut sutured manifold hierarchy.

Proof. Eliminate index-zero disks in $(M, \gamma)$ so that the resulting sutured manifold $(M_1, \gamma_1)$ has $C(M_1, \gamma_1) = \hat{C}(M_1, \gamma_1) = \hat{C}(M, \gamma)$ (4.13(b)). Doing self-amalgamations last guarantees the annuli satisfy 4.18(c). By 4.3–4.5 $(M_1, \gamma_1)$ is still $\beta_1$-taut. If $H_2(M_1, \partial M_1) = 0$ then stop. Otherwise there is, by 2.6, a conditioned surface $S_2$ in some component of $M_1$ such that

(a) $[S_2, \partial S_2] \neq 0$ in $H_2(M_1, \partial M_1)$,
(b) $S_2$ decomposes $M_1$ to a $\beta$-taut sutured manifold $(M_2, \gamma_2)$, and
(c) $S_2$ contains no separating closed component.

Then apply 4.17 first to a component $S$ of $S_2$ for which $[S, \partial S] \neq 0$ in $H_2(M_1, \partial M_1)$ and then to the other components of $S_2$. This replaces the component of $M_1$ in which $S_2$ lies with components in $M_2$ all of which have lower reduced complexity. Continue in this manner until $H_2(M_n, \gamma_n)$ is trivial (perhaps because the reduced complexity is trivial as in 4.13(c)). This sequence, with all amalgamations and cancellations of arcs in $\beta$ ignored, is the required series of decompositions.

5. Warm-up application: Satellite knots of winding number zero have property P

The first application is particularly easy because $\beta = \emptyset$. The principal result is also a consequence of the more general theorem (§9) that all satellite knots have property P.

Let $M$ be an irreducible cobordism between tori $T_0$ and $T_1$ with the property that any torus $T' \subset M$ which separates $T_0$ from $T_1$ is $\partial$-parallel. (The more general criterion that $M$ is "Sp-atoroidal" suffices, see [4].) Let $M^\varphi$ be the 3-manifold obtained from $M$ by attaching $D^2 \times S^1$ to $T_1$ via a framing $\varphi : \partial D^2 \times S^1 \to T_1$. Inclusion induces a natural homomorphism $\Phi : H_2(M, T_0) \to H_2(M^\varphi, T_0)$.

5.1 Theorem. (a) If some $M_{\varphi_0}$ is reducible then for any $\varphi \neq \varphi_0$, $M_\varphi$ is irreducible and the Thurston norm $x$ satisfies $x(\Phi(\alpha)) = x(\alpha)$ for every $\alpha \in H_2(M, T_0)$.

(b) If $M_\varphi$ is irreducible for every $\varphi$, then for any $\alpha$ in $H_2(M, T_0)$ there is a framing $\varphi_\alpha$ such that if $\varphi \neq \varphi_\alpha$ then $x(\Phi(\alpha)) = x(\alpha)$.

Proof. Regard $(M, \partial M)$ as a sutured manifold with $T_0$ a suture and $T_1$ in $R_+$. Let $(S, \partial S) \subset (M, T_0)$ be an incompressible surface for which $\chi_-(S) = x(\alpha)$ and $[S, \partial S] = \alpha$. With no loss of generality we can assume that $\partial S$ consists of a possibly empty collection of coherently oriented parallel simple closed curves.

Construct a taut sutured manifold sequence

$$(M, T_0) \xrightarrow{S_1} (M_1, \gamma_1) \xrightarrow{S_2} \cdots \xrightarrow{S_i} (W_i, \gamma_i) \xrightarrow{S_{i+1}} \cdots$$

so that $S_1 = S$, each $S_i$ is conditioned or a collection of product disks and annuli disjoint from $T_1$, and $S_i$ contains no separating closed components. By 2.6 such a sequence can be extended so long as $H_2(W_i, \partial W_i - T_1) \neq 0$, and by 4.17 the extension can be made to decrease reduced complexity. Hence eventually the sequence terminates in $(M_n, \gamma_n)$ with $H_2(M_n, \partial M_n - T_1) = 0$. 

Then it is an easy consequence of duality that \( \partial M_\infty \) is the union of \( T_1 \), at most one other torus \( T' \) and a collection of spheres.

Since \( M \) was assumed irreducible, each sphere in \( \partial M_\infty \) bounds a ball in \( M_\infty \), and there is a single component \( H \) of \( M_\infty \) with \( \partial H = T' \cup T_1 \). Since \( M \) was assumed atoroidal, either \( H = T_1 \times I \) or \( T' \) is parallel to \( T_0 \) in \( M \). The latter is impossible, since in that case \( S \) would necessarily have been in the collar between \( T_0 \) and \( T' \), and so null-homologous in \( H_2(M, T_0) \). Therefore \( H = T_1 \times I \).

As in the proof of 3.9, \( T' \) cannot lie entirely in \( R(\gamma_n) \), so \( \gamma_n \) contains a nontrivial collection of essential curves in \( T' \). Let \( H^\varphi \) be the manifold obtained by attaching \( D^2 \times S^1 \) to \( H \) via \( \varphi \). Then \( H^\varphi = D^2 \times S^1 \) with \( \partial H^\varphi = T' \).

In particular, unless \( \varphi \) is attached by that framing \( \varphi_0 \) which makes \( \gamma_n \cap T' \) meridians of \( H^\varphi \), the induced sutured manifold structure on \( H^\varphi \) is taut.

For each \( 1 \leq i \leq n \) let \( M^\varphi_i \) denote the manifold obtained by attaching \( D^2 \times S^1 \) to \( M \) via \( \varphi \). Then for every \( \varphi \neq \varphi_0 \) the \( S_i \) above induce a sutured manifold sequence

\[
(M^\varphi, T_0) \xrightarrow{S_1} (M^\varphi_1, \gamma_1) \xrightarrow{S_2} \cdots \xrightarrow{S_n} (M^\varphi_n, \gamma_n)
\]

in which the last term is taut. Then by 3.9 \( (M^\varphi_1, \gamma_1) \) is taut, and so, by 3.3, \( S_1 \) is taut in \( M^\varphi \).

5.2 Corollary. Suppose \( k \) is a knot in \( S^1 \times D^2 \) of winding number zero, and some nontrivial surgery on \( k \) produces a manifold \( N \) which is homeomorphic to \( S^1 \times D^2 \). Then \( k \) lies in a 3-ball.

Proof. Case 1. Any torus in \( M = S^1 \times D^2 - N(k) \) separating \( S^1 \times \partial D^2 \) from \( N(k) \) is \( \partial \)-parallel in \( M \).

\[\text{Figure 5.1}\]
Proof of Case 1. If \( M \) is \( \partial \)-reducible, then \( k \) lies in a 3-ball, so assume \( M \) is \( \partial \)-irreducible. Since \( K \) has winding number 0, there is a surface \( (S, \partial S) \subset (M, S^1 \times \partial D^2) \) for which \( \partial S \) is a meridian circle \( \{p\} \times \partial D^2 \).

Since \( M \) is a \( \partial \)-irreducible, \( S \) cannot be a disk and so its homology class has nontrivial Thurston norm. But after filling in a solid torus at \( \mathcal{N}(k) \) in two distinct ways, \( \partial S \) becomes a meridian of a solid torus. Hence \([S, \partial S]\) is representable by a meridian disk, and so has trivial norm, in both cases. This contradicts 5.1.

Case 2. The general case: Suppose \( T \subset M \) is any torus which separates \( S^1 \times \partial D^2 \) from \( \mathcal{N}(k) \). Then \( T \) is compressible in \( S^1 \times D^2 \) and \( N \). If there is a compressing disk in the component of \( M - T \), which contains \( S^1 \times \partial D^2 \), then after the compression \( T \) bounds a 3-ball containing \( k \). Assume then, on the contrary, that each torus \( T \subset M \) which separates \( S^1 \times \partial D^2 \) from \( \mathcal{N}(k) \) compresses in the component of \( S^1 \times D^2 - T \) and of \( N - T \) which contain \( \partial \mathcal{N}(k) \), so that the component is in both cases a solid torus. Then a maximal collection of pairwise nonparallel tori in \( M \) bounds in \( S^1 \times D^2 \) a nested collection of solid tori \( \mathcal{N}(k) \) of \( W_0 \subset W_1 \subset \cdots \subset W_n = S^1 \times D^2 \).

(They bound a similar nested collection in \( N \).) Let \( w_i \) denote the winding number of \( W_i \) in \( W_{i+1} \). Then the product of all \( w_i \) is 0, the winding number of \( k \) in \( S^1 \times D^2 \). Let \( W_i \subset W_{i+1} \) be the innermost successive pair for which \( w_i = 0 \). Then \( W_{i+1} - W_i \) is an irreducible, \( \partial \)-irreducible cobordism between two tori such that filling a solid torus on \( \partial W_i \) with two distinct framings gives a solid torus. (The framings are distinct because the winding number of \( k \) in \( W_i \) is nontrivial.) The proof then proceeds as in Case 1.

6. Reduction lemmas

In 4.3 and 4.5 we showed that under certain conditions components of \( \beta \) can be removed without affecting \( \beta \)-tautness. The purpose of this section is to develop a few more examples of such reduction lemmas. The examples shown here are specifically designed for application in §8. Different applications may call for different reduction lemmas.

6.1 Definition. Let \((Q, \partial Q)\) be a surface in \((M_\beta, \gamma_\beta)\) in normal position. A \( \beta \)-loop in \( Q \) at point \( b \) in \( \beta \) is a proper arc \( \alpha \) essential in \((Q, \partial Q \cap \mathcal{N}(\beta))\) such that both ends of \( \alpha \) lie on the meridian disk of \( \mathcal{N}(\beta) \) at \( b \). A disk \( D \) in \( M_\beta \) whose boundary is the union of the \( \beta \)-loop and an arc of the meridian at \( b \) is called a \( \beta \)-loop compressor.

6.2 Y-reduction. Suppose \((M, \gamma, \beta)\) is a sutured manifold for which a component \( \beta_0 \) of \( \beta \) is a tree with three ends: \( \varepsilon_1 \) and \( \varepsilon_2 \) in \( R_+ \) and a third in \( R_- \).
Figure 6.1

Suppose further that there is a surface \((Q, \partial Q) \subset (M_\beta, \partial M_\beta)\) with the properties:

(i) \(Q\) is a disk.
(ii) \(\partial Q\) lies entirely in \(R_+ \cup \partial \mathcal{N}(\beta_0)\).
(iii) Each component of \(\partial Q \cap \partial \mathcal{N}(\beta_0)\) is an arc with one end at \(\varepsilon_1\) and the other at \(\varepsilon_2\).

Figure 6.2

Lemma. If \((M, \gamma)\) is \(\beta\)-taut then either \(\partial Q \subset R_+\), or there are compressible \(\beta\)-loops for \(Q\) at both \(\varepsilon_1\) and \(\varepsilon_2\).
Proof. View $\beta_0$ as the union of an arc $\delta_+$ with ends at $\epsilon_1$ and $\epsilon_2$ in $R_+$ and an arc $\delta_-$ with one end on $\delta_+$ and the other on $R_-$. Then there is a tubular neighborhood $\eta \subset \mathcal{N}(\beta_0)$ of $\delta_+$ which intersects $\delta_-$ (hence $\beta$) in a single point and whose complement in $\mathcal{N}(\beta_0)$ is a neighborhood of the arc $\delta_- - \eta$. Let $S$ be the manifold obtained from $R_+$ by 1-surgery on $\eta$. Then $\chi_\beta(S) = \chi_\beta(R_+) + 1$. Since $\partial Q \subset R_+ \cup \partial \mathcal{N}(\beta_0)$, $Q$ can be isotoped so that $\partial Q \subset S$.

![Figure 6.3](image)

If $\partial Q$ were essential in $S$ or bounded a disk intersecting $\beta$ more than once, then either (a) 2-surgery on $S$ via $Q$ would produce a surface $S'$ with $\chi_\beta(S') = \chi_\beta(S) - 2 = \chi_\beta(R_+) - 1$, contradicting the $\beta$-tautness of $R_+$, or (b) $\chi_\beta(R_+) = 0$. In the latter case either $S'$ is a sphere intersecting $\beta$ in a single point or a component of $\partial Q \cap R_+$ is a compressible $\beta$-loop. So suppose $\partial Q$ bounds a disk $F$ in $S$ with $|F \cap \beta| \leq 1$.

Let $C$ denote the boundary of a meridian disk of $\mathcal{N}(\beta)$ at $\epsilon_1$, say. Then some outermost arc of $C$ in $F$ cuts off a disk $F'$ from $F$ disjoint from $\beta$, and $\partial F' \cap \partial F$ is a $\beta$-loop of $Q$ at $\epsilon_1$ for which $F'$ is a $\beta$-loop compressor.

6.3 Noose reduction. Suppose $(M, \gamma)$ is a sutured manifold for which a component $\beta_0$ of $\beta$ is a "noose", i.e., a circle at the end of an arc, with its end $\epsilon$ in $R_+$.

Suppose further that there is a surface $(Q, \partial Q) \subset (M_0, \partial M_0)$ with the properties:

(i) $Q$ is a disk.
(ii) $\partial Q$ lies entirely in $R_+ \cup \partial \mathcal{N}(\beta_0)$.
(iii) Each component of $\partial Q \cap \partial \mathcal{N}(\beta_0)$ is an arc (with its end at $\epsilon$).
Lemma. If \((M, \gamma)\) is \(\beta\)-taut, then either \(\partial Q \subset R_+\) or there is a compressible \(\beta\)-loop for \(Q\) at any point in \(\beta\).

Proof. The proof is an easy analogue of 6.2, where for \(\eta\) we take all of \(\mathcal{N}(\beta_0)\).

6.4 \(H\)-reduction. Suppose \((M, \gamma, \beta)\) is a sutured manifold, with \(\partial M\) a union of spheres. Suppose that \(\beta\) is \(H\)-shaped; that is, \(\beta\) consists of three segments \(\beta_l, \beta_r\) and \(\beta_c\) with the following properties:

(a) \(\beta_l\) and \(\beta_r\) each have one endpoint \((\varepsilon_l^+\) and \(\varepsilon_r^+\) respectively) in \(R_+\) and one endpoint \((\varepsilon_l^-\) and \(\varepsilon_r^-\) respectively) in \(R_-\).

(b) \(\beta_c\) has one endpoint in \(\beta_l\) and one endpoint in \(\beta_r\).

Suppose further that there is a surface \((Q, \partial Q) \subset (M_\beta, \partial M_\beta)\) consisting of three disk components \(Q_l, Q_r\) and \(Q_0\) with the properties:

(i) \(Q_l\) (resp. \(Q_r\)) is a disk which would cancel \(\beta_l\) (resp. \(\beta_r\)) into a suture on \(\gamma\), if \(\beta_l\) (resp. \(\beta_r\)) had been an arc component of \(\beta\) (see 4.1).

(ii) \(\partial Q_0\) lies entirely in \(R_+ \cup \partial \mathcal{N}(\beta)\).

(iii) Each component of \(\partial Q \cap \partial \mathcal{N}(\beta)\) is an arc with its ends at distinct ends of \(\mathcal{N}(\beta)\).
Lemma. If $(M, \gamma)$ is $\beta$-taut, then either
(a) $\partial Q_0 \subset R_+$,
(b) there are compressible $\beta$-loops for $Q_0$ at $\varepsilon_i^+$ and $\varepsilon_r^+$, or
(c) $(M, \gamma)$ is taut (in the Thurston norm).

Proof. Claim 1. With no loss of generality, every disk component of $R(\gamma)$ contains an endpoint of $\beta$.

Proof of Claim 1. If there is a disk component $C$ of $R(\gamma)$ which is disjoint from $\beta$, then the other component $C'$ of $R(\gamma)$ whose boundary lies on the same annular suture as $\partial C$ must also be a disk disjoint from $\beta$, since $R(\gamma)$ is $\beta$-incompressible. Then since $M$ is $\beta$-taut (hence $\beta$-irreducible), $C \cup C'$ bounds a ball in $M$ disjoint from $\beta$, and so this component is taut in the Thurston norm.

Claim 2. No arc of $\partial Q_0 \cap R_+$ has both ends at $\varepsilon_i^+$ or both at $\varepsilon_r^+$.

Proof of Claim 2. Such an arc $\alpha$ at $\varepsilon_i^+$, say, would divide the component of $\partial M$ in which it lies into two disks. If either disk is disjoint from $\beta$, then it is a $\beta$-loop compressor for $\alpha$. Hence one disk $D'$ contains two ends of $\beta$ and the other disk $D$ only one. Moreover, $\beta_r$ cannot have one end in $D$ and the other in $D'$, since $Q_r$ is disjoint from $Q_0$. Hence $\varepsilon_r^-$ lies in $D$. Pushing $D$ into $M$ along the disk $Q_i$ then produces a $\beta$-loop compressor for $\alpha$.

Conclusion of Proof. From Claim 2 it follows that every arc of $\partial Q_0 \cap R_+$ runs between an end of $\beta_i$ and an end of $\beta_r$. There is a component $C_0$ of $R_+$ containing two ends of $\beta$ and components $C_l$ and $C_r$ (possibly identical) containing respectively a single end of $\beta_i$ and a single end of $\beta_r$. Each of the latter shares a common suture with $C_0$. By Claim 1 at least two of these components must be disks, and $\partial M$ is a single 2-sphere. If $C_0$ is not a disk, then $C_l$ and $C_r$ are both disks, and $C_0$ is an annulus sharing a common suture with each of $C_l$ and $C_r$. Then $\chi_{\beta}(R_-) = 0 \neq 2 = \chi_{\beta}(R_+)$, contradicting the tautness of $R_+$. Hence $C_0$ is a disk and, since either $C_l$ or $C_r$ is also a disk and shares a common suture with $C_0$, $\partial M$ must have a single suture, and so is taut in the Thurston norm.

7. Parametrizing surfaces

Here we show how to carry information about the topology of a sutured manifold down through a hierarchy. The idea is to start with a surface $Q$ in $M_\beta$ and follow it as it is cut up during a sutured manifold decomposition. The reducing lemmas of §§4 and 6 can then be applied to its remnants in the last term of the decomposition to eliminate components of $\beta$. 
7.1 Definition. Let \((M, \gamma, \beta)\) be a sutured manifold. A parametrizing surface \((Q, \partial Q) \subset (M, \partial M)\) is a surface such that no component of \(Q\) is a disk with boundary in \(R_\pm\).

7.2 Definition. Let \((Q, \partial Q)\) be a parametrizing surface for a \(\beta\)-taut sutured manifold \((M, \gamma)\) and suppose \((S, \partial S) \subset (M, \partial M)\) is a \(\beta\)-incompressible \(d\)-surface. Then \(S\) is normalized if the following hold:

(a) \(\partial S\) and \(\partial Q\) have been isotoped on \(T(\gamma)\) and near \(A(\gamma)\) so that the number of points in \(\partial S \cap \partial Q\) lying in \(A(\gamma) \cup T(\gamma)\) is as small as possible. (Thus, for example, no arc (circle) component of \(\partial Q\) in \(A(\gamma)\) intersects any arc (resp. circle) component of \(\partial S\) in \(A(\gamma)\).)

(b) Every simple closed curve of \(S \cap Q\) is essential in \(Q\).

7.3 Lemma. Let \((Q, \partial Q)\) be a parametrizing surface for a \(\beta\)-taut sutured manifold \((M, \gamma)\) and suppose \((S, \partial S) \subset (M, \partial M)\) is a \(\beta\)-incompressible \(d\)-surface. Then there is an isotopy normalizing \(S\). Furthermore restricted to any component of \(A(\gamma), T(\gamma)\) or \(R(\gamma)\), the isotopy of \(\partial S\), is proper.

Proof. (a) is immediate.

The proof of (b) is by induction on the number of simple closed curves in \(S \cap Q\). It is a standard innermost disk argument, utilizing the \(\beta\)-incompressibility of \(S\) and the \(\beta\)-irreducibility of \(M\).

7.4 Definition. Let \(Q\) be a parametrizing surface with \(\nu\) the number of essential arcs in \(\partial Q \cap A(\gamma)\), and \(\mu\) the number of essential arcs in \(\partial Q \cap \mathcal{N}(\beta)\). Let \(\kappa\) be a function which assigns a real number to each arc \(\lambda\) in \(\partial Q \cap \mathcal{N}(\beta)\) and \(\mathcal{K} = \sum_{\lambda} \kappa\). (\(\kappa\) can be chosen arbitrarily, but a good choice can help exposition.) Define the index of \(Q\) as

\[ I(Q) = \nu + \mu + \mathcal{K} - 2\chi(Q). \]

7.5 Lemma. Let \((Q, \partial Q)\) be a parametrizing surface for a \(\beta\)-taut sutured manifold \((M, \gamma)\) and suppose \((S, \partial S) \subset (M, \partial M)\) is a conditioned surface which decomposes \((M, \gamma)\) into a \(\beta\)-taut sutured manifold. Let \((M', \gamma', \beta')\) be the sutured manifold obtained by decomposing \(M\) along \(S_{k,l}\) (cf. 3.7). For \(k\) and \(l\) sufficiently large and \(S_{k,l}\) normalized with respect to \(Q\), the surface \(Q' = Q - \mathcal{N}(S_{k,l})\) is a parametrizing surface in \((M', \gamma', \beta')\) with \(I(Q') = I(Q)\).

Proof. Note that \((M', \gamma')\) is \(\beta'\)-taut by 3.8.

Claim 1. For \(k, l\) sufficiently large, and \(S_{k,l}\) normalized with respect to \(Q\), no component of \(Q'\) is a disk with boundary in \(R_\pm\).

Proof of Claim 1. Let \(\varepsilon_+ \subset \partial Q\) denote the 1-manifold \(R_+ \cap \partial Q\) and \(\varepsilon_-\) the 1-manifold \(R_- \cap \partial Q\). Every component of \(\varepsilon_\pm\) has a transverse orientation inherited from that of \(R_\pm\). Choose in \(Q\) disjoint collar structures \(\varepsilon_\pm \times I\) near \(\varepsilon_\pm\) so that \(S \cap (\varepsilon_\pm \times I)\) consists entirely of a collection of \(I\) fibers, and the normal field to \(\varepsilon_\pm\) in the collar is always tangent to the \(I\)-fibers.
Using a partition of unity, average together near \( S \cap (\varepsilon_{\pm} \times I) \) the vector field tangent to the \( I \)-fibers and the normal vector field to \( S \) in \( Q \). The result is a nontrivial vector field \( \nu \) on \( \varepsilon_{\pm} \times I \) which is transverse to \( S_{k,l} \cap (\varepsilon_{\pm} \times I) \) for all \( k, l \geq 0 \). The double curve sums used in the construction of \( S_{k,l} \) will be taken to lie within these collars, so that for all \( k, l \geq 0 \) \( (S_{k,l} \cap Q) - (\varepsilon_{\pm} \times I) = (S \cap Q) - (\varepsilon_{\pm} \times I) \).

The proof of Claim 1 is now by induction on the number \( p \) of components of \( (S \cap Q) - (\varepsilon_{\pm} \times I) = (S_{k,l} \cap Q) - (\varepsilon_{\pm} \times I) \). Suppose a component of \( Q' \) is a disk \( D \) with \( \partial D \subset (R_{+} \approx S_{k,l}) \), say. Then \( \partial D \) lies entirely inside of \( S_{k+1,l} \) and so is removed when \( S_{k+1,l} \) is normalized. Since \( \partial D \) cannot lie entirely in \( R_{+} \), \( \partial D \) must contain an arc of \( (S_{k,l} \cap Q) - (\varepsilon_{\pm} \times I) \). Then, after normalization, \( |(S_{k+1,l} \cap Q) - (\varepsilon_{\pm} \times I)| < p \). Continue, if necessary, until \( |(S_{k',l'} \cap Q) - (\varepsilon_{\pm} \times I)| = 0 \). Then, if \( D \) is a disk in \( Q - \mathcal{N}(S_{k',l'}) \) the argument just given shows \( \partial D \subset \varepsilon_{\pm} \times I \). It follows that \( D \subset \varepsilon_{\pm} \times I \). But this is impossible, for \( \nu \) would then be a normal vector field to \( \partial D \) extending to a vector field over all of \( D \).

**Claim 2.** \( I(Q') = I(Q) \).

**Proof of Claim 2.** In general \( S_{k,l} \cap Q \) consists of a disjoint collection of arcs and circles in \( Q \), but it suffices to assume \( S_{k,l} \cap Q \) is connected.

If \( S_{k,l} \cap Q \) is a circle, then no term in the definition of \( I(Q) \) is changed when \( \mathcal{N}(S_{k,l}) \) is removed.

If \( S_{k,l} \cap Q \) is an arc \( \alpha \) then \( \chi(Q') = \chi(Q) + 1 \). The set of components \( \lambda \) of \( \partial Q' \cap \mathcal{N}(\mathcal{Z}_{\beta}) \) is the same as that in \( \partial(Q) \cap \mathcal{N}(\mathcal{Z}_{\beta}) \), since \( S_{k,l} \) is disjoint from \( \mathcal{N}(\mathcal{Z}_{\beta}) \) so \( \mathcal{H} = \sum_{\lambda} \kappa \) is unchanged. If an end of \( \alpha \) lies in \( \mathcal{N}(\beta) \) then \( \mu \) for \( Q' \) is 1 greater than \( \mu \) for \( Q \). If an end of \( \alpha \) lies in \( A(\gamma), T(\gamma) \) or \( R_{\pm} \) (hence in general in \( \partial M \)), then one side or the other of the component of \( \partial S \) in which \( \alpha \) terminates becomes a suture of \( \gamma' \). Hence \( \nu \) for \( Q' \) is 1 greater than \( \nu \) for \( Q \). Thus in general \( \nu + \mu \) for \( Q' \) is 2 greater than \( \nu + \mu \) for \( Q \). By 7.5, the index \( I \) remains unchanged.

**7.6.** Let \( (Q, \partial Q) \) be a parametrizing surface for a \( \beta \)-taut sutured manifold \((M, \gamma)\), and suppose \((S, \partial S) \subset (M, \partial M)\) is a product disk or \( \beta \)-incompressible product annulus normalized with respect to \( Q \). Let \( \Delta \) be the collection of arcs of \( S \cap Q \) which have both ends in either \( R_{+}(\gamma) \) or \( R_{-}(\gamma) \). Do 2-surgeries on \( Q \) via outermost disks of \( S \), and cut off by the arcs of \( \Delta \) until \( \Delta = \emptyset \); then remove all disks of \( Q \) whose boundaries lie entirely in \( R_{\pm}(\gamma) \). Call the result \( Q_{c} \). Let \((M', \gamma', \beta')\) be the sutured manifold obtained by decomposing \( M \) along \( S \).

**Lemma.** The surface \( Q' = Q_{c} - \mathcal{N}(S) \) is a parametrizing surface in \((M', \gamma', \beta')\) with \( I(Q') \leq I(Q) \).
Proof. Suppose there was a disk component $D$ of $Q'$ with its entire boundary in $R_+ (\gamma ')$. By construction $\partial D$ must intersect $S_+$, the side of $\mathcal{M} (S)$ lying in $R_+ (\gamma ')$. If it lay entirely in $S_+$, it would contradict the normalization of $S$ with respect to $Q$. If only one part lay in $S_+$ then, since $\partial D$ does not cross the suture lying at one end of $S_+$, it would contain an arc in $S_+$ with both ends on the other end of $S_+$, contradicting the construction of $S_e$. Hence $Q'$ is a parametrizing surface.

Since $Q$ is a parametrizing surface, no disk removed in the construction of $Q_e$ was originally in $Q$. Hence the number of disks removed is no larger than $\Delta$. Thus $\chi (Q_e) \geq \chi (Q)$, so $I (Q') \leq I (Q)$.

7.7 Definition. A $\beta$-taut sutured manifold hierarchy for $(M, \gamma, \beta)$ respects a parametrizing surface $Q$ if at each stage in the hierarchy either $S_i$ is a product disk or nontrivial product annulus and $Q_i$ is constructed from $Q_{i - 1}$ as in 7.6, or $S_i$ is a conditioned surface and the surface $Q_i = Q_{i - 1} \cap M_i$ is still a parametrizing surface. Notice that this guarantees that always $\partial Q_i \cap \mathcal{M} (\beta_i) = \partial Q \cap \mathcal{M} (\beta_i)$ and $I (Q_i) \leq I (Q)$.

7.8 Theorem. If $Q$ is a parametrizing surface for the $\beta$-taut sutured manifold $(M, \gamma)$, then there is a $\beta$-taut sutured manifold hierarchy for $(M, \gamma)$ which respects $Q$.

Proof. The proof is similar to that of 4.19, with 3.8, 7.5, and 7.6 applied so that each successive $Q_i$ remains a parametrizing surface.

8. Application II: Genus of knots is supperadditive under band sum

Let $\beta$ be the planar "eyeglass" 1-complex consisting of two circles $\beta_t$ and $\beta_r$ (bounding disjoint disks in the plane) and an arc $\beta_c$ joining them. Regard $\beta$ as a complex in $\mathbb{R}^2 \subset \mathbb{R}^3$, and let $P$ and $W$ be regular neighborhoods of $\beta$ in $\mathbb{R}^2$ and $\mathbb{R}^3$ respectively, so that $P$ is a properly imbedded planar surface in the genus two handlebody $W$. $\partial P \subset \partial W$ has three components: Two of them, denoted $c_l$ and $c_R$, are parallel in $P$ to $\beta_t$ and $\beta_r$ respectively. Denote the third by $c_0$.

8.1. Suppose $\beta$ is imbedded in a 3-manifold $M$ for which $\partial M$ is a torus. Regard $W$ as a regular neighborhood of $\beta$ in $M$. Suppose that $M$ is $\beta$-irreducible and there is an incompressible, $\partial$-incompressible surface $Q, \partial Q) \subset (M - \hat{W}, \partial W)$ consisting of 3-components: $Q_r$, $Q_l$, and $Q_0$ with the following properties:

(a) $Q_r$ ($Q_l$) is an annulus for which one boundary component is $c_r \subset \partial W$ ($c_l \subset \partial W$), and the other is an essential curve in the torus $\partial M$. 
(b) $Q_0$ is a planar surface, all of whose $\partial$-components are parallel to $c_0$ in $\partial W$.

(c) There is no compressible $\beta$-loop (6.1) in $Q$ at a point on $\beta_l$ ($\beta_r$).

(d) No sphere intersects $\beta$ in a single point of $\beta_c$.

8.2 Theorem. If $(S, \partial S) \subset (M, \partial M)$ is $\beta$-taut, then $S \cap \beta_c = \emptyset$ and $S$ is taut in the Thurston norm.
Proof. Let $S$ be such a surface, and construct a $\beta$-taut sutured manifold hierarchy

$$(M, \partial M) \xrightarrow{S_1} (M_1, \gamma_1) \xrightarrow{S_2} \cdots \rightarrow (M_n, \gamma_n)$$

respecting $Q$. Following 2.4, the edges $\beta_r, \beta_l$ and $\beta_c$ can be oriented so that at any point of intersection with an $S_i$ (hence with $R(\gamma_1)$) the orientation points in the direction of the normal vector to $S_i$. For each arc $\lambda$ of $\partial Q \cap \mathcal{N}(\mathcal{Y})$ define $\kappa(\lambda) = -1$ if $\lambda$ passes between an edge of $\beta$ pointing into the vertex and one pointing out, and define $\kappa(\lambda) = -2$ if $\lambda$ passes between edges of $\beta$ both pointing into the vertex or both pointing out.

![Figure 8.3](image)

Note that the curve $c_0 \subset \partial W$ has, in the terminology of 7.4, $\nu = 0$, $\mu = 4$, and $\kappa = -6$, and the curves $c_r, c_l$ each have $\nu = 0$, $\mu = 1$, $\mathcal{H} = -1$. Hence if $Q_0$ has $p$ boundary components, $\chi(Q) = 2 - p$ and so $I(Q) = -2p + 2p - 4 = -4$.

Claim 1. $S_i \cap \beta_c = \emptyset$ for all $i$.

Suppose not, and let $k \geq 0$ be the smallest integer for which $S_k \cap \beta_c \neq \emptyset$. Denote by $\eta_k$ the regular neighborhood $W \cap M_k$ of the 1-complex $\beta \cap M_k$. There are two components of $\eta_k$, which contain vertices. These components are either $Y$-shaped or noose-shaped (see §6), depending on whether or not $\beta_l$ and $\beta_r$ have been cut by some $S_i$. For the remainder of the argument we will assume they are $Y$-shaped, for if they are noose-shaped the only change would be the application of 6.3 instead of 6.2. Let $\eta_+$ (resp. $\eta_-$) denote the component with two ends in $R_+$ (resp. $R_-$) and one end in $R_-$ (resp. $R_+$).

Every component of $\partial Q_0 \cap \eta_{\pm}$ in $M_k$ is an arc passing through two edges and one vertex, so for any such component $\mu + \kappa \geq 0$. Moreover, the inequality is strict unless $\kappa = -2$, i.e., both ends of the arc lie in either $R_+$ or $R_-$. Any component of $\partial Q_0$, which contains an arc in $\eta_{\pm}$ with one end in $R_+$ and one end in $R_-$, must contain either another such arc or an arc crossing a suture,
so for the component $\nu + \mu + \mathcal{H} \geq 2$. Since $I(Q_k) \leq I(Q) = -4$, it follows from 7.4 that some component $q$ of $Q_k$ is a disk in which $\partial q$ never passes from $R_+$ and $R_-$. With no loss of generality we may then assume that $\partial q$ is contained in $R_+ \cup \eta_+$.

Since $q$ is a part of a parametrizing surface, $\partial q$ does not lie in $R_+$ (7.1). Then 6.2 applied to $\eta_+$ and $q$ produces a compressible $\beta$-loop for $Q_k$ (hence for $Q$) at a meridian of $\beta_l$ or $\beta_r$. This contradicts 8.1(c).

Claim 2. No product annuli coming from self-amalgamations need to be used in the above hierarchy.

Proof of Claim 2. Since $\beta_c$ is left intact during the decompositions, the only arc components of $\beta$ produced during the decomposition are pieces of $\beta_l$ or $\beta_r$, but these are immediately cancellable via the remnants of $Q_l$ or $Q_r$.

Claim 3. $S$ is taut in the Thurston norm.

Proof of Claim 3. $\partial M_n \cap \beta \neq \emptyset$ since $M$ is $\beta$-irreducible. Hence for some $i$, $S_i \cap \beta \neq \emptyset$. By the previous claim, $S_i$ then intersects $\beta_r$ or $\beta_l$ hence $Q_r$ or $Q_l$. It follows from the $\beta$-tautness of $S_i$ that each arc of $S_i \cap Q_r$ and $S_i \cap Q_l$ must have one end in $\partial W$ and one end in $\partial M$. Hence $S_i$ intersects one of the circles $Q_r \cap \partial M$ or $Q_l \cap \partial M$. These circles must be parallel in the torus $\partial M$, since $Q_r$ and $Q_l$ are disjoint, so $S_i$ must intersect both $Q_r \cap \partial M$ and $Q_l \cap \partial M$. Reversing the argument, it follows that $S_i$ intersects both $\beta_r$ and $\beta_l$, so $\beta_n$ is a 1-complex which is the union of arcs parallel to sutures (via the remnants of $Q_l$ and $Q_r$ in $M_n$) and an $H$-shaped component as in 6.4.

Then, as in Claim 1, the component $q$ of $Q_n$ of negative index is a disk as in (ii) and (iii) of 6.4. Components of $Q_l \cap M_n$ and $Q_r \cap M_n$ satisfy 6.4(i). Again $\partial q$ does not lie entirely in $R(\gamma_n)$. Then from 6.4 we conclude that $(M_n, \gamma_n)$ is taut in the Thurston norm.

Since each $S_i$ is either conditioned or a product disk, and contains no separating closed components, and $M_1$ is not a solid torus, it follows from 3.9 that $(M_1, \gamma_1)$ is taut in the Thurston norm. Thus 3.3 (with $\beta = \emptyset$) implies $S$ is taut in the Thurston norm.

8.3 Definition. For knots $K_0$ and $K_1$ in $S^3$, let the band sum of $K_0$ and $K_1$ be defined as follows: Imbed $K_0$ and $K_1$ into disjoint 3-balls in $S^3$. Let $b: I \times I \to S^3$ be an imbedding such that $b^{-1}(K_i) = I \times \{i\}$, $i = 0, 1$. Then join $K_0 - b(I \times \{0\})$ to $K_1 - b(I \times \{1\})$ by the arcs $b(\partial I \times I)$. The resulting knot is the band sum of $K_0$ and $K_1$ along $b$ and is denoted $K_0 \#_b K_1$.

8.4 Theorem. $\text{genus}(K_0 \#_b K_1) \geq \text{genus}(K_0) + \text{genus}(K_1)$.

Proof. Let $\lambda$ be a cocore of the band $b$. It is an arc with both ends on $K = K_0 \#_b K_1$. A sphere $S^2$ separating $K_0$ from $K_1$ in $S^3$ intersects the band $b$ in arcs parallel to $\lambda$. Choose $S^2$ so that $|S^2 \cap K|$, and hence the number of
these arcs is as small as possible among such separating spheres. (The number is odd, hence never trivial.)

Let $\eta$ be a tubular neighborhood of $K$. Let $\beta_c = \lambda - \eta$ and $\beta_l, \beta_r$ be disjoint meridians of $\eta$, which pass through the ends of $\beta_c$. The union of the band $b(I \times I) \cap M$ and disjoint collar neighborhoods of $\beta_l$ and $\beta_r$ is naturally homeomorphic to $\beta \times I$, and those collar neighborhoods may be chosen so that they contain $S^2 \cap \eta$. Let $W$ be a regular neighborhood of $\beta \times I$ and $Q_0$ be the planar surface obtained from $S^2$ by removing $\eta \cup W$. Let $Q'_r$ and $Q'_l$ be meridians of $\eta$. Now let $\eta'$ be a tubular neighborhood of $K$ contained in $\eta$, $M = S^3 - \eta'$, $Q_r = Q'_r - \eta'$ and $Q_l = Q'_l - \eta'$.

Let $S$ be a $\beta$-taut Seifert surface for $K_0 \#_b K_1$ in $M$. Then by 8.2, $S$ is disjoint from $\beta_c$, hence from the band, and is taut in the Thurston norm. The latter implies genus($S$) = genus($K_0 \#_b K_1$). Since $S$ is disjoint from the band, we may attach $b(I \times I)$ to $S$ and obtain a surface $S'$ with genus($S'$) = genus($S$). Furthermore $\partial S'$ is the union of a longitude of $K_0$ and a longitude of $K_1$. Then a standard innermost disk argument shows that $S'$ may be isotoped so that every circle of intersection with $S^2$ is essential in $S'$. After some compressions of $S'$ it will be made disjoint from $S^2$ and so the union of disjoint Seifert surfaces for $K_0$ and $K_1$.

8.5 Remark. In case of equality, all the last compressions must be along parallel simple closed curves in $S'$. But in that case, we can assume all the compressing disks lie on one side of $S'$. Push the band, which lies in $S'$, off
to the other side. This makes the band disjoint from minimal genus Seifert surfaces for \( K_0 \) and \( K_1 \).

**8.6 Corollary** ([11], [13]). If \( K_0 \neq_b K_1 \) is the unknot, then each of \( K_0 \) and \( K_1 \) is the unknot, and the band sum is a connected sum.

We wish to generalize 8.6 to a more general statement about links. This can be done via the combinatorial route of [11] but also follows with ease from the previous argument.

**8.7 Definition.** A complete system of spheres \( Q \) in a 3-manifold \( M \) is an imbedded collection of incompressible, pairwise nonparallel spheres so that any other incompressible sphere in \( M - Q \) is parallel to a component of \( Q \) (cf. [8, 3.14]). An example: If \( M \) is the connected sum of \( k \) irreducible 3-manifolds, then any complete system contains exactly \( 2k - 3 \) components.

**8.8 Definition.** For \( L \) an oriented link in \( S^3 \), a band operation on \( L \) is defined as follows: Let \( b: I \times I \to S^3 \) be an imbedding such that \( b^{-1}(L) = I \times \partial I \) with the orientation inherited from \( \partial(I \times I) \). Then \( L - b(I \times I) \) is a link denoted by \( L_b \).

**8.9 Proposition.** Let \( L' = L_b \) for some band operation on the link \( L \). There is either a complete system \( Q \) for \( S^3 - L \) disjoint from the band \( b \) or a Seifert surface \( S \) for \( L \) containing \( b(I \times I) \) for which \( S - b(I \times I) \) is a taut Seifert surface for \( L' \).

*Proof.* Choose the complete system \( Q \) to minimize \( |b \cap Q| \).

**Claim 1.** With no loss of generality, we can assume \( b \) intersects every component of \( Q \).

*Proof of Claim 1.* Let \( S' \) be a taut Seifert surface for \( L' \). Let \( Q' \) be the union of all components of \( Q \) which are disjoint from \( b \). Then \( Q' \cap L' = \emptyset \). Since \( S' \) is taut, every component of \( S' \cap Q' \) is inessential in \( S' \). Thus \( S' \) can be altered by 2-surgery so that it is still taut and disjoint from \( Q' \). Discard \( Q' \) and all components of \( L' \) which lie in the components of \( S^3 - Q' \) not containing \( b \). If the theorem is true for the remaining links, it will be true for the original links.

Let \( M = S^3 - L' \), and let \( \beta \) be the eyeglass 1-complex imbedded in \( M \) as in the proof of 8.4.

**Claim 2.** \( M \) is \( \beta \)-irreducible.

*Proof of Claim 2.* Suppose there were a sphere in \( M \), disjoint from \( \beta \), bounding no 3-ball disjoint from \( \beta \). Among all such spheres, let \( P \) be one for which \( |P \cap Q| \) is minimal. Let \( Q' \) be obtained from \( Q \) by 2-surgery along an innermost disk at \( P \). Since no component of \( Q' \) is disjoint from \( \beta \), neither is any component of \( Q' \). Moreover, \( |Q' \cap b| = |Q \cap b| \), and \( Q' \) contains a
complete system of spheres with one fewer component. This contradicts our assumption that \( Q \) minimizes \(|Q \cap b|\).

Now the argument proceeds just as in the case of 8.4. Ultimately there is a Seifert surface \( S' \) for \( L' \), which is taut and disjoint from \( b(I \times I) \). Then \( S = S' \cup b(I \times I) \) is the required Seifert surface.

**8.10 Corollary.** If \( L' = L_b \) is the unlink, then either \( b \) is disjoint from some complete system of spheres for \( S^3 - L \) or \( L \) bounds a collection of disks disjoint from \( b \) (i.e., \( L \) is the unlink and \( b \) is the trivial connected sum).

**Proof.** If \( b \) fails to be disjoint from some complete system for \( L \) then, by 8.9, \( L' \) bounds a collection of disks \( S' \) which are disjoint from the band.

If the components of \( b(\partial I \times I) \) lie on different components of \( L' \), then \( S = S' \cup b(I \times I) \) is a collection of disks whose boundary is \( L \). Thus \( L \) is the unlink and \( b \) clearly is disjoint from a complete system of spheres for \( L \).

Suppose then the components of \( b(\partial I \times I) \) lie on the same component \( l \) of \( L' \). The union of \( b(I \times I) \) and the component of \( S' \) that \( l \) bounds is an annulus \( A \) such that \( A \cap L = \partial A \). If any component of \( Q \cap A \) is a closed curve inessential in \( A \), then 2-surgery on the disk bounded by an innermost such curve provides a collection of 2-spheres containing a complete system having no more intersections with \( b \) and fewer intersections with \( A \). So we can assume \( Q \cap A \) contains only essential curves in \( A \). Then 2-surgery on the disk in \( Q \) bounded by an innermost circle of \( Q \cap A \) changes \( S = S' \cup b(I \times I) \) into a collection of disks, disjoint from \( b \), whose boundary is \( L \).

**8.11 Corollary.** If \( L' = L_b \), and both \( L \) and \( L' \) are the unlink, then \( b \) is a trivial band (i.e., after an isotopy, \( L, L', \) and \( b \) all lie in a plane).

**Proof.** If the components of \( b(I \times \partial I) \) lie on different components of \( L \), then \( b \) intersects any complete system of spheres for \( S^3 - L \). Thus by 8.10 the band is trivial.

If the components of \( b(I \times \partial I) \) lie on the same component of \( L \), then the components of \( b(\partial I \times I) \) lie on different components of \( L' \). Switch the roles of \( L \) and \( L' \), and this case follows from the previous one.

9. Application III: Satellite knots have property P

Let \((M, \partial M)\) be a 3-manifold with \( \partial M \) a torus and \( H_1(M) \) torsion free. Let \( \beta \) be a knot in \( M \) with tubular neighborhood \( \mathcal{N} \). Suppose \( M \) is \( \beta \)-irreducible, and the manifold \( M^\beta \), obtained from \( M \) by performing some nontrivial surgery on \( \beta \), also has \( H_1(M^\beta) \) torsion-free. Suppose finally that \( M^\beta \) is \( \partial \)-reducible.

**9.1 Theorem.** Any \( \beta \)-taut surface \((S, \partial S) \subset (M, \partial M)\) is taut in the Thurston norm.
9.2 Corollary. If \( k \) is a knot contained in the tubular neighborhood \( K \times D^2 \) of a knot \( K \) in \( S^3 \), then either

(a) \( k \) is contained in a 3-cell in \( K \times D^2 \),

(b) \( k \) is isotopic in \( K \times D^2 \) to \( K \times \{0\} \),

(c) \( K \) is unknotted in \( S^3 \), or

(d) no manifold obtained from \( S^3 \) by surgery on \( k \) is a homotopy 3-sphere.

Proof of 9.2 from 9.1. If the winding number \( \omega(k) > 1 \), then the corollary follows immediately from [2]. So henceforth suppose \( \omega(k) = 1 \) or 0.

Take for \( M \) the tubular neighborhood \( K \times D^2 \), let \( \beta \) be the knot \( k \), and for \( S \) take a \( \beta \)-taut surface whose boundary is a meridian \( \{\text{pt.}\} \times \partial D^2 \) of \( K \times \partial D^2 \) and whose geometric intersection with \( \beta \) is its algebraic intersection. Suppose a manifold obtained by surgery on \( k \) is a homotopy 3-sphere. Then \( K \times \partial D^2 \) is compressible in the manifold, so either \( K \) is unknotted in \( S^3 \) (condition (c)) or \( M^\varphi \) is \( \partial \)-reducible and \( H_1(M^\varphi) \) is torsion free. In the latter case the theorem applies, and \( S \) is taut in \( M \), hence is a meridian disk. Then \( k \) intersects a meridian of \( K \times D^2 \) always with the same orientation. If \( \omega(k) = 0 \) then (a) holds. If \( \omega(k) = 1 \) then \( k \) is the knot sum of \( K \) and the arc \( k - \mathcal{N}(S) \) in the 3-ball \( (K \times D^2) - \mathcal{N}(S) \). If the latter is unknotted (b) holds; if it is knotted, \( k \) is a composite, so (d) holds [1]. q.e.d.

The proof of 9.1 relies on Lemmas 9.3 and 9.6 which give criteria for detecting homology torsion in 3-manifolds.

9.3. Let \( M \) be a \( \beta \)-irreducible 3-manifold, \( \beta \) a simple closed curve in \( M \) with neighborhood \( \mathcal{N}(\beta) \), and \( (Q, \partial Q) \subset (M_\beta, \partial M_\beta) \) a planar surface whose boundary is a collection of \( p \) nonmeridional essential curves in \( \partial \mathcal{N}(\beta) \) and at most one other curve in \( \partial M \).

Lemma. Suppose there is a disk \( D \) in \( M \), which intersects \( \beta \) nontrivially in the interior of \( D \) so that all points of intersection of \( \beta \) with \( D \) have the same orientation. Then either

(a) \( D \) contains a compressing or \( \partial \)-compressing disk for \( Q \) in \( M_\beta \),

(b) \( Q \) is homologous (rel the curve \( Q \cap \partial M \) if it exists) to a planar surface \( Q' \) with \( \partial Q' \) a proper subset of \( \partial Q \), and the manifold \( \overline{M} \) obtained by performing Dehn surgery on \( \beta \) with slope that of \( \partial Q \) contains a Lens-space summand, or

(c) \( |Q \cap \partial D| \geq p \).

Proof. Label the boundary components of \( \partial Q \) in \( \partial \mathcal{N}(\beta) \) with the label 1, \( \cdots \), \( p \) in order around the torus. We assume \( Q \cap D \) contains no \( \beta \)-inessential circles in \( D \), for if an innermost circle is also \( \beta \)-inessential in \( Q \) it can be removed by an isotopy of \( Q \), and if it is essential (a) is satisfied.

Consider the graph \( \Gamma \) in \( D^2 \) whose vertices are the points of \( \beta \cap D \) and whose edges are the arcs of \( D \cap Q \) (where some ends of edges lie on \( \partial D \), not just at the vertices). Each end of each arc on a vertex has a label in \( \{1, \cdots, p\} \)
corresponding to the component of ∂Q to which it belongs. All labels appear in the same order (always counterclockwise or always clockwise) some fixed number of times (depending on the slope of ∂Q on β) around each vertex, since β intersects D always with the same sign.

Either (c) or there is some label x ∈ {1, · · · , p} for which every edge of Γ with end labelled x has its other end lying on a vertex (i.e., not on ∂D). Then Γ contains a “great x-cycle” as in [2, 2.6]. Then the simple combinatorial argument of [2, 2.6.2] shows that among the disk components in the complement of Γ there is a disk which either ∂-compresses Q in Mβ or winds algebraically more than once around the boundary of a solid torus in M. In the latter case there is a Lens-space summand in M, providing a cobordism between Q and the required planar surface Q' (cf. [2, 2.5.2]). q.e.d.

The second lemma requires a bit of linear algebra:

9.4 Definition. An n × n matrix A is decomposable if, for some permutation matrix P, PAP^T = (b 0 0 b), and the square matrix B is called a (proper) summand of A.

Let A_{ii} denote the (i,i)-minor of A, called a principal minor.

9.5 Lemma. Let A be an n × n integral matrix such that for all i

0 ≠ |a_{ii}| ≥ ∑_{j≠i} |a_{ij}|.

Then either

1. some summand B of A (possibly all of A) has |b_{ii}| = ∑_{j≠i} |b_{ij}| and |	ext{det}(B_{ii})| ≥ 2 for every i,
2. |det A| ≥ 2, or
3. some |a_{ii}| = 1.

Proof of 9.5. The proof is by induction on n. Note that either (2) or (3) is satisfied when n = 1.

First suppose A decomposes as above for B and C. Then B and C each satisfy the theorem by inductive hypothesis. If either B or C satisfies (1) or (3), so does A. If both satisfy (2), so does A.

Next suppose A is indecomposable. Then every minor of A satisfies the theorem by inductive hypothesis. (1) cannot be satisfied for any principal minor A_{ii}, for such a summand of A_{ii} would be a (proper) summand of A. If (3) holds for any principal minor, it holds for A. So henceforth assume (2) holds for every principal minor: |det A_{ii}| ≥ 2.

Suppose A is indecomposable and |a_{ii}| = ∑_{j≠i} |a_{ij}| for all i. Since |det(A_{ii})| ≥ 2 for every i, (1) holds for A (taking B = A).

Suppose A is indecomposable and |a_{ii}| > ∑_{j≠i} |a_{ij}| for at least one i. Then the real matrix A' obtained from A by replacing a_{ii} by a_{ii} ± (1/|det A_{ii}|)
continues to satisfy $|a_{ij}^*| > \sum_{j \neq i} |a_{ij}|$, so, by [10, III 2.2.4],

$$|\det A| \neq 0 \neq |\det A'| = |(\det A) \pm 1|.$$ 

Hence $|\det A| \geq 2$ and (2) holds for $A$. q.e.d.

Lemma 9.5 has the following topological consequence:

9.6 Lemma. Let $N$ be a manifold obtained by attaching $n$ 2-handles $q_1, \ldots, q_n$ to a solid handlebody $H$ of genus $n$. Regard $H$ as obtained by attaching $(n + 1)$ 1-handles to two 0-handles. Let $c_0, \ldots, c_n$ be the cocores of these 1-handles of $H$. Suppose the intersections satisfy the following conditions:

1. $|\partial q_i \cap c_i| \geq \sum_{0 \leq j \neq i} |\partial q_i \cap c_j|$.
2. For each $1 \leq i \leq n$, every intersection point of $\partial q_i$ with $c_i$ has the same orientation.

Then either

(a) some $q_i$ intersects $c_i$ and another $c_k$ in a single point, and is disjoint from all other $c_j$, or

(b) $N = N' \neq W$, where $H_1(W)$ has nontrivial torsion.

Proof. Let $A$ denote the $n \times n$ integral matrix whose entry $a_{ij}$ is the algebraic intersection number $\langle \partial q_i, c_j \rangle$, $1 \leq i, j \leq n$. Condition (2) guarantees that $|a_{ii}|$ is also the geometric intersection number of $|\partial q_i \cap c_i|$. Hence (1) implies that for all $1 \leq i \leq n$, $|a_{ii}| \geq \sum_{j \neq i} |a_{ij}|$. Now apply 9.5:

In this context, 9.5(3) implies 9.6(a). Also 9.5(2) implies that $\partial N$ is a sphere and $|H_1(N)| = |\det A|$, so $H_1(N)$ is finite and nontrivial.

So suppose 9.5(1) holds. With no loss of generality, the curves involved in the matrix $B$ are $c_1, \ldots, c_r$ and $\partial q_1, \ldots, \partial q_r$ for some $1 \leq r \leq n$. From the equality $|b_{ii}| = \sum_{j \neq i} |b_{ij}|$ we conclude that each $q_i$, $1 \leq i \leq r$, is disjoint from $c_0$ and each $c_j$, $j > r$. Then the union of the 0-handles of $H$, the 1-handles $c_1, \ldots, c_r$, and the 2-handles $q_1, \ldots, q_{r-1}$ is a summand $W$ of $N$ with $|H_1(W)| = |\det(A_{rr})| \geq 2$. Hence $H_1(W)$ is finite and nontrivial.

Proof of 9.1. Regard $M$ as a sutured manifold with $\partial M$ a suture. Since $M$ is $\beta$-irreducible, $M$ is a $\beta$-taut sutured manifold. Let $(S, \partial S) \subset (M, \partial M)$ be $\beta$-taut. By capping off annuli in $\partial M$, modify $S$ so that it is a $d$-surface (this modification does not change the Thurston norm). The restriction of a $\partial$-reducing disk in $M^\varrho$ to $M - \mathcal{N}$ is a $\partial$-incompressible, incompressible planar surface $Q$ in $M - \mathcal{N}$ with $\partial Q$ the union of a single essential circle on $\partial M$ and a family of $p$ parallel essential circles of $\partial \mathcal{N}$. Hence $Q$ is a parametrizing surface. Construct a $\beta$-taut sutured manifold hierarchy

$$(M, \partial M) \xrightarrow{S_1} (M_1, \gamma_1) \xrightarrow{S_2} \cdots \xrightarrow{S_i} (M_i, \gamma_i) \xrightarrow{S_{i+1}} \cdots$$
which respects \( Q \). The sequence terminates with a 3-manifold \( M_n \) with \( \partial M_n \) a collection of spheres. We will be focusing attention on \((M_n, \gamma_n, \beta_n)\) and for simplicity continue to refer to \( \beta_n \) as \( \beta \).

Let \( q_1, \ldots, q_r \) be the components of \( Q_n \), and for each \( 1 \leq \lambda \leq r \) let \( \nu_\lambda \) and \( \mu_\lambda \) denote, as in 7.4, the number of arcs in \( \partial q_\lambda \cap A(\gamma_n) \) and \( \partial q_\lambda \cap \beta \) (edges of \( \beta \)) respectively. Then, since there are no vertices in \( \beta \), \( I(q_\lambda) = (\nu_\lambda + \mu_\lambda) - 2\chi(q_\lambda) \).

Since \( Q_n \) is a parametrizing surface, no \( q_\lambda \) is a disk with boundary disjoint from \( \gamma_n \) and \( \beta \), so always \( I(q_\lambda) \geq 0 \). By 7.5 and 7.6, \( \sum I(q_\lambda) \leq I(Q) = -2\chi(Q) = 2p - 2 \).

Let \( \{q'_\lambda\} \) be the collection of amalgamating and cancelling disks in \( Q_n \). Let \( \beta' \) be the collection of arcs obtained from \( \beta \) by amalgamating and cancelling the \( \beta \), using the \( q'_\lambda \) one at a time but never doing a self-amalgamation. Since self-amalgamations are never performed, this operation never uses product annuli, so \((M_n, \gamma_n)\) is unchanged. By 4.3 and 4.4 \((M_n, \gamma_n, \beta_n)\) is still \( \beta' \)-taut.

9.7 Main Lemma. \( \beta' = \emptyset \).

Proof of 9.1 from 9.7. Then \((M_n, \gamma_n)\) is taut in the Thurston norm. We wish to show that every decomposition \((M_{i-1}, \gamma_{i-1}) \overset{S_i}{\rightarrow} (M_i, \gamma_i)\) is a taut decomposition also in the Thurston norm. Suppose \( S_i \) is the last one which is not. Then from 4.18(a) and 3.9(b), \( S_i \) is a \( \beta \)-nontrivial product annulus in which both ends are inessential in \( R(\gamma_{i-1}) \). \( S_i \) thus lies in a sphere component of \( \partial M_i \) containing a single suture. Since \( M_i \) is taut, the sphere bounds a 3-ball \( M \). \( M \) contains arcs of \( \beta \) running between \( R_+ \) and \( R_- \) since \( S_i \) is not \( \beta \)-trivial. By 4.18(c) none of these arcs of \( \beta \) is parallel to the suture. No matter how \( M \) is further decomposed later in the sequence by product disks or annuli, a ball containing arcs of \( \beta \) not parallel to the suture will persist. The resulting ball \( M_n \) in \( M_n \) would contradict the claim that \( \beta' = \emptyset \).

Proof of 9.7. By \( \beta' \)-irreducibility of \( M_n \), any component of \( \partial M_n \) which is disjoint from \( \beta' \) bounds a ball disjoint from \( \beta' \), so, unless some component of \( \partial M_n \) intersects \( \beta' \), \( \beta' \) is empty and we are done. Let then \( N \) be a component of \( \partial M_n \) which intersects \( \beta' \).

Before the amalgamations and cancellations, the points \( \beta \cap N \), the sutures \( \gamma_n \), and the arcs of \( \partial Q_n \cap (N - \gamma_n) \) can be regarded as a type of graph \( \Gamma \) in \( N \). In the following discussion a vertex of \( \Gamma \) will be a point of \( \beta \cap N \), and an edge of \( \Gamma \) is an arc component of \( \partial Q_n \cap (N - \gamma_n) \) with each end either at a vertex or at a suture of \( \gamma_n \).

After the amalgamations and cancellations, the graph \( \Gamma \) is converted into a new graph \( \Gamma' \) whose vertices are the points \( \beta' \cap N \) and edges come from those components of \( \partial Q_n \cap (N - \gamma_n) \) which do not lie on amalgamating or cancelling disks. In fact, \( \Gamma' \) is obtained from \( \Gamma \) in two operations:
(a) Contract those edges of $\Gamma$ which lie on amalgamating disks.

(b) Let $e$ be an edge of $\Gamma$, which lies on a cancelling disk, and $v_\pm$ its two vertices. $v_\pm$ also are the ends of a component $\beta_0$ of $\beta$ which is cancelled. Any edge of $\Gamma$ (other than $e$) incident to $v_+$ is connected to an edge incident to $v_-$ via an arc of $\partial Q_n \cap \mathcal{N}(\beta_0)$. Remove $e$ and $v_\pm$, and in a band neighborhood of $e$ connect ends of edges contiguous to $v_+$ to the corresponding ends of edges contiguous to $v_-$. We will denote by $(Q', \partial Q') \subset (M_{\beta'}, \partial M_{\beta'})$ the components of $Q_n$ which are not amalgamating or cancelling disks. Since these disks have index zero, still $I(Q') \leq 2p - 2$.

9.8 Definitions. For $v$ a vertex of $\Gamma'$, let the star of $v$, denoted by $\text{st}(v)$, be the set of all edges of $\Gamma'$ with a single end at $v$ (thus loops are not included). Let the valence $\rho(v) = |\text{st}(v)|$. A vertex $v$ is full if $\rho(v) \geq p$.

Let $\delta$ be a suture in $\gamma_n$. Let $\text{st}_\pm(\delta)$ be the set of all edges of $\Gamma'$, which lie in $R_\pm$ and have a single end in $\delta$. Similarly $\rho_\pm(\delta) = |\text{st}_\pm(\delta)|$ and $\delta$ is $\pm$full if $\rho_\pm(\delta) \geq p$.

A loop in $\Gamma'$ is inessential if it bounds in $N$ a disk containing no other vertex of $\Gamma'$ and no suture.

9.9 Remark. No suture $\delta$ of $\gamma_n$ can bound a disk in $N$ disjoint from $\beta'$, for by $\beta'$-tautness both components of $R_\pm$ adjacent to $\delta$ would then be disks disjoint from $\beta'$, contradicting our choice of $N$. Hence if a loop contains no vertices in its interior (i.e., the disk it bounds), then it is inessential.

Claim 1. If $v$ is a vertex of $\Gamma'$ on which no essential loops are based, then $v$ is full.

Proof of Claim 1. Every loop on $v$ is inessential by hypothesis. Let $D_v$ be a regular neighborhood in $N$ of the union of $v$ and the interiors of all loops based at $v$. Then $D_v$ contains no vertices but $v$, and $\partial D_v$ intersects $\rho(v)$ edges on $\Gamma$. Thus $D_v$ corresponds, before the amalgamation and cancellation of disks of $Q_n$, to a disk satisfying the hypotheses of 9.3, but not conclusions (a) or (b). But (c) implies that $v$ is full.

Claim 2. Let $\delta$ be a suture in $N$, dividing $N$ into two disks. Let $D$ be the disk containing, say, that component of $R_+$ which is adjacent to $\delta$. If the vertices of $\Gamma'$ lying in $D$ lie entirely in either $R_+$ or $R_-$, then $\delta$ is $+\text{full}$.

Proof of Claim 2. If there are no cancelling disks, then before amalgamation, the disk $D$ satisfies the hypotheses of 9.3, but not conclusion (a) or (b). Conclusion (c) implies that $\delta$ is $+\text{full}$.

If there is a cancelling disk $q_\lambda$ whose edge $e$ in $\Gamma$ has one or both vertices $v_\pm$ in $D$, then these vertices do not necessarily lie in $R_+$ ($R_-$), so the above argument does not work. If $e$ crosses $\delta$, then alter $D$ by removing a regular neighborhood of $e$. This removes $v_\pm$ from $D$ and further ensures that $\partial D \cap \Gamma$
is unaffected by the cancellation. If \( e \subset D \), push \( D \) into \( M_\alpha \) using a regular neighborhood of \( q_\lambda \). The resulting disk does not contain \( v_\pm \). After further pushes along amalgamating disks contiguous to \( q_\lambda \), eventually \( D \) can be made to satisfy the hypotheses of 9.3 and to have its boundary intersect \( \Gamma \) before amalgamation and cancellation just as \( \delta \) intersects \( \Gamma' \) afterwards.

**Claim 3.** If \( v \) and \( w \) are both vertices in \( \Gamma' \cap R_+ \) (or \( \Gamma' \cap R_- \)) and are both full, then \( v \) and \( w \) are adjacent in \( \Gamma' \).

**Proof of Claim 3.** Suppose \( v \) and \( w \) are not adjacent, and consider a component \( \alpha \) of \( \partial Q' \) containing \( s \) edges of \( \Gamma' \) incident to \( v \) and \( t \) edges of \( \Gamma' \) incident to \( w \), \( s + t \geq 1 \). Then \( \alpha \) must contain at least \( 2(s + t) \) arcs of intersection with \( \gamma_n \) or \( \mathcal{N}(\beta') \). That is, in the terminology of 7.4, \( \mu_\alpha + \nu_\alpha \geq 2(s + t) \). This implies \( \mu_\alpha + \nu_\alpha \geq s + t + 2 \) unless \( \mu_\alpha + \nu_\alpha = 2 \) and \( s + t = 1 \).

More generally, for any component \( q_\lambda \) in \( Q' \) for which \( \partial q_\lambda \) contains \( s \) edges of \( \Gamma' \) incident to \( v \) and \( t \) edges of \( \Gamma' \) incident to \( w \), \( s + t \geq 1 \), either \( I(q_\lambda) \geq s + t \) or \( I(q_\lambda) = 0 \), \( q_\lambda \) is a disk, and \( s \) (or \( t \)) = 1. But in the latter case \( q_\lambda \) would be a cancelling or (nonself)amalgamating disk for the component of \( \beta' \) with end at \( v \) (or \( w \)). This is impossible by construction of \( \beta' \). Hence always \( I(q_\lambda) \geq s + t \).

Summing over all components of \( Q' \) we get \( 2p - 2 \geq I(Q') \geq \rho(v) + \rho(w) \geq 2p \), a contradiction.

**Claim 4.** If \( v \in R_\pm \), and \( \delta \) is a \( \pm \)full suture, then there is an edge in \( \Gamma' \) with ends in \( \delta \) and \( v \).

**Proof of Claim 4.** Essentially the same as that of Claim 3.

**Claim 5.** All essential loops in \( \Gamma' \) and all sutures are parallel.

**Proof of Claim 5.** By 9.9 any disk in \( N \) bounded by an essential loop or a suture contains vertices of \( \Gamma' \), therefore vertices on which no essential loop is based, and hence full vertices (Claim 1). If not all essential loops and sutures were parallel, there would then be at least three full vertices, no pair of which are adjacent, but two of which would both lie in either \( R_+ \) or \( R_- \), contradicting Claim 3.

**Definition.** Following Claim 5, there are only two disk components of \( R(\gamma_n) \). By 9.9 and Claim 3, one must be in \( R_+ \) and one in \( R_- \), so we denote them \( D_\pm \).

**Claim 6.** An innermost essential loop in \( \Gamma' \) contains sutures in its interior, so every vertex in \( D_\pm \) is full.

**Proof of Claim 6.** If not, then by Claim 5 the loop lies in the interior of \( D_+ \), say. By Claim 2, \( \partial D_+ \) is a \( + \)full suture. Since the loop is essential, it contains in its interior a full vertex (Claim 1). Hence \( \delta \) and \( v \) contradict Claim 4.

**Claim 7.** All vertices inside an innermost essential loop of \( \Gamma' \) lie in \( D_+ \) or \( D_- \).
Proof of Claim 7. By Claim 5, the loop $\lambda$ has, say, $D_+$ in its interior and $D_-$ in its exterior. If there is a vertex $v$ inside $\lambda$, then $v$ either lies in $D_+$ or is adjacent to neither vertices in $D_+$ nor vertices in $D_-$, contradicting Claim 3.

Claim 8. There are no essential loops in $\Gamma'$.

Proof of Claim 8. Choose an innermost essential loop $\lambda$ in $\Gamma$ and let $v$ be its vertex. If $|\text{st}(v) \cap (\text{interior } \lambda)| < p$ then, by Claim 7, $(\text{interior } \lambda)$ can be modified as $D$ was in the proof of Claim 2 so that it corresponds, before the amalgamation and cancellation of disks of $Q_n$, to a disk satisfying the hypotheses of 9.3, but not the conclusion. If $|\text{st}(v) \cap (\text{interior } \lambda)| \geq p$, then $v$ is full and so, by Claim 3, must lie in $D_\pm$. This contradicts Claim 6.

Claim 9. Every vertex is in $D_+$ or $D_-$.

Proof of Claim 9. Every vertex is full by Claims 8 and 2, hence every vertex is adjacent to either a vertex of $D_+$ or a vertex of $D_-$ by Claim 2.

Claim 10. $N$ contains only one suture $\delta$.

Proof of Claim 10. This follows immediately from Claims 2, 4 and 9.

Claim 11. For every component $\beta_i$ of $\beta'$ there is a disk component $q_i$ of $Q'$ such that $\partial q_i$ crosses alternately from $D_+$ to $D_-$ via $\beta_i$ and from $D_-$ back to $D_+$ via $\{\delta\} \cup \{\beta' - \beta_i\}$.

Proof of Claim 11. Let $v$ be the end of $\beta_i$ in $D_+$, say. For $\alpha$ any component of $\partial Q'$, $2|\alpha \cap \text{st}(v)| \leq \mu_\alpha + \nu_\alpha$ since arcs of $\alpha \cap R(\gamma_n)$ lie in $R_+$ and $R_-$ alternately. Let $q_\lambda$ be a component of $Q'$. Sum over all components $\alpha$ of $\partial q_\lambda$ to get

$$|\partial q_\lambda \cap \text{st}(v)| \leq I(q_\lambda)/2 + \chi(q_\lambda).$$

If for all $\lambda$ either the inequality is strict or $\chi(q_\lambda) \leq 0$, then always $|\partial q_\lambda \cap \text{st}(v)| \leq I(q_\lambda)/2$. Summing over all $q_\lambda$ we would thus get $p \leq p - 1$, a contradiction.

Hence there is a $q_i$ which is a disk and for which $|\partial q_i \cap \text{st}(v)| = I(q_\lambda)/2 + 1$. That is, for $\alpha = \partial q_i$, $|\alpha \cap \text{st}(v)| = (\mu_\alpha + \nu_\alpha)/2$, so every arc of $\alpha \cap R_+$ lies in $\text{st}(v)$. This proves the claim.

Now apply 9.6 to the punctured solid handlebody $(\partial N) \cup (\cup \mathcal{N}(\beta'))$, with each $c_i, i \geq 1$, corresponding to a meridian disk of $\mathcal{N}(\beta_i)$ and $c_0$ corresponding to $\delta$. Since there are no amalgamating or cancelling disks among the $q_i$, 9.6(a) cannot occur. But conclusion 9.6(b) is also impossible since $W \subset M_n \subset M$. Hence the contradiction completes the proof.
10. Afterword: The Poenaru conjecture is true

Can surgery on a knot in $S^3$ yield $S^1 \times S^2$? The so-called "Property R conjecture" is that the answer is no for all but the unknot. The Poenaru conjecture is stronger, and is best stated from the opposite direction: Can surgery on a reducible homology $S^1 \times S^2$ ever yield $S^3$? The conjecture is that the answer is no unless the manifold is $S^1 \times S^2$ and the knot is a standard $S^1 \times \text{(point)} \subset S^1 \times S^2$.

The proof of the conjecture follows with remarkable ease from the combinatorics of §9.

10.1 Theorem. Let $M$ be a closed, reducible 3-manifold with $H_\ast(M) = H_\ast(S^1 \times S^2)$. Suppose there is a knot $\beta$ in $M$ such that some surgery on $\beta$ produces $S^3$. Then $M = S^1 \times S^2$, and $\beta$ is isotopic in $M$ to $S^1 \times \text{(point)}$.

Proof. It is easy to see that $\beta$ generates $H_1(M)$. Any $\beta$-reducing sphere in $M$ is then separating, and would cut off a summand of $M$ which persists in $S^3$. Hence $M$ is $\beta$-irreducible, and so $\beta$-taut. $M$ viewed as a sutured manifold with $\beta = \emptyset$ is not taut in the Thurston norm since $M$ is reducible. If there were an incompressible, $\partial$-incompressible, planar surface $(Q, \partial Q) \subset (M_\beta, \partial M_\beta)$ with $\partial Q$ not meridian circles, then the argument of §9 could be applied verbatim to derive a contradiction.

We do not know that such a surface $Q$ exists. But examination of the argument of §9 shows that in fact it is not necessary that $Q$ be incompressible or $\partial$-incompressible, but only that no compressing or $\partial$-compressing disks lie in $R(\gamma_n) \subset \partial M_n$, the boundary of the last stage of the $\beta$-taut sutured manifold hierarchy (cf. 9.3(a)). That such a planar surface exists follows from the following remarkable lemma of Gabai (cf. [5, §4]). The knot $k$ in $S^3$ is that obtained by surgery on $\beta$, and $P$ is $\partial M_n - \mathcal{N}(\beta)$.

10.2 Lemma. Suppose $k$ is a knot in $S^3$, and

$$(P, \partial P) \subset (S^3 - \mathcal{N}(k), \mathcal{N}(k))$$

is a properly imbedded surface, with $\partial P$ a nonempty collection of nonmeridian essential curves. Then either $k$ is the unknot or there is a planar surface $(Q, \partial Q) \subset (S^3 - \mathcal{N}(k), \mathcal{N}(k))$ with $\partial Q$ a nonempty collection of meridians of $\mathcal{N}(k)$ such that $P$ contains no compressing or $\partial$-compressing disks for $Q$.

Before embarking on a proof we need some preliminary machinery.

10.3 Definition. A knot $k$ is in generic position if the projection $h : R^3 \to R$ has only nondegenerate critical points and no two critical points are at the same height. Suppose $k$ has $2b$ critical points, and $Q_1, \ldots, Q_{2b-1}$ are level planes for $h$, one between each pair of critical levels. Let $t(k) = \sum_{i=1}^b |Q_i \cap k|$. A knot $k$ with height function $h$ is in thin position if $t(k)$ is minimal over all generic knots isotopic to $k$. Clearly $t(k) = 2$ if and only if $k$ is the unknot.
Suppose $k$ is a generic knot in $S^3$, and $Q$ is a level plane for $h$. A \textit{+disk} (resp. \textit{−disk}) is a disk in $S^3$ whose interior is disjoint from $k$ and whose boundary is the union of an arc $\alpha_+$ ($\alpha_-$) in $k$ lying above (below) $Q$ and an arc $\delta_+$ ($\delta_-$) lying in $Q$.

**10.4 Lemma.** If for a generic knot $k$ and a level plane $Q$ there is a $+\text{disk}$ and a disjoint-$\text{disk}$, then $k$ is not in thin position.

**Proof.** The two disks may be used to isotope $\alpha_\pm$ to $\delta_\pm$. Then push $\delta_+$ slightly below $Q$, and $\delta_-$ slightly above. This decreases $t$ by at least 2.

**Proof of 10.2.** Put $k$ in thin position. Isotope $P$ so that all its critical points occur at different heights. Let $Q_+$ be a level plane located just below the highest critical point of $k$. Then $Q_+ \cap P$ contains arc components. If every arc component of $Q_+ \cap P$ were essential in $P$ then, after some 2-surgeries on $Q_+$ along 2-disks in $P$, $Q_+$ would become the required planar surface. So we assume that some arc component $\delta$ of $Q_+ \cap P$ is inessential in $P$ and so cuts off from $P$ a disk $D_+$ with $\partial D_+$ the union of $\delta$ and an arc $\alpha$ of $k$. If $\alpha$ lies below $Q_+$, then clearly $k$ is trivial. Hence we assume $\alpha$ lies above $Q_+$, so $D_+$ is a $+\text{disk}$.

Similarly, we can assume that a level plane $Q_-$ just above the lowest critical point for $k$ cuts off from $P$ a $-\text{disk}$.

![Figure 10.1](image)

**FIGURE 10.1**

Now if $Q$ is any plane between $Q_+$ and $Q_-$, then $Q \cap P$ contains arcs. If all are essential in $P$, then we are done as in the case of $Q_+$ above. If there are essential arcs cutting off both $+\text{disks}$ and $-\text{disks}$, then by 10-4 $k$ would not be in thin position. Hence somewhere there is a level plane $Q$ between $Q_+$ and $Q_-$, so that a slightly higher plane cuts off a $+\text{disk} D_+$ but no $-\text{disk}$, and a slightly lower plane cuts off a $-\text{disk} D_-$ but no $+\text{disk}$. Thus $Q$ must
contain a saddle singularity of $P$, and $\alpha_+$ and $\alpha_-$ are adjacent segments of $k - Q$. Hence $D_+$ and $D_-$ can be used to isotope $\alpha_+ \cup \alpha_-$ into an arc near $Q$ reducing the number of critical points of $k$ (and hence $t(k)$) by at least 2. The contradiction proves the lemma.
